PREFACE

More people are interested today, than at any other time, in the study of classical Indian Music A few of the Indian Universities have already included Indian Music as a regular subject in their courses of study and some others are thinking of following suit There are however not many books which may satisfy the requirements of an academic study of Indian Music and hence fresh books written from an academic point of view are all the more welcome

A few years ago the present writer published one such book in Marathi and then it was well received both by the Public and by the Press It saw the light of the day evidently through the noble patronage of the Chief Saheb of Ichalkaranji and later on received further encouragement from the Sangli and Miraj (Sr & Jr) States and from the Gwalior Durbar in particular Consequently, the author s study of Indian Music, which, for him, has been a matter of mere hobby, had an added sense of some moral obligation and duty towards the public The present book then needs no other apology It is in fact the outcome of such a study, actuated by a sense of thankfulness and gratitude for the appreciation shown and encouragement given to the author by the patrons and by the public alike

The reader is requested to note, at the very outset, that for the purposes of the present book, Indian Music should be taken to mean Hindustbāni Music

only, or that music which is at present current in Northern India Again, as the author has no first hand knowledge of the niceties either of the Kannada language or of the Karnataki or Southern system of Indian Music, his remarks in that quarter should, if necessary, be taken at some discount It is however hoped that a good many of the things discussed may provide due interest even to those belonging to the Southern School A similar view should also be taken of what the author has said about the Music of the West

As for the plan of the book, it is fundamentally different from that of the former book Firstly, it is written in English, so as to serve a much wider public interested in Indian Music Secondly, being academic in its presentation, it has a limited field in view, viz of Indian Music as a pure study * Lastly, it is written with the firm belief that the academic study of any scientific subject first means a thorough grasp of its first principles, which as a matter of course should enable its student to understand and explain its various developments This last

* The book therefore carefully avoids giving any tips such as those which the music caterer of today wants, or such other references which pertain to practical music only Further, it deals with the theory of the system as a whole and hence bestowe no consideration upon this or that particular Raga, although references to a few well known Ragas would no doubt have made the discussion of certain principles simpler Readers, who are more immediately interested in practical music, will find all the required information in the author's Marathi book, which may serve as a fitting companion to the present volume

view point has necessitated the adoption of a new feature viz the incorporation of the first principles governing the dual aspect (as a Science and as a Fine Art) of music as a part and parcel of an academic study of Indian Music While going through the book, the reader will see that these principles, when so adopted, at once reveal to us the physical and artistic bearings of a majority of the practices and conventions of Indian Music

Physics and Æsthetics are apparently the two departments governing Music, whereas, tradition, inheritance and other cultural associations have always influenced its growth to a considerable extent The earlier chapters of the book therefore deal with the Physics of Music and the later ones with its Æsthetics, while the fourth chapter, which takes stock of the cultural reactions on Indian Music, acts as the connecting link, as it were, between the two This may then explain the arrangement of the chapters of the book

As for the subject matter, the reader will find that the book contains a number of original topics and provides an altogether new basis for the intonation and other subsequent developments of Indian Music The author is however conscious that an attempt like the present one is bound to have many weaknesses Thus the best course for investigating the intonation of Indian Music would be to take sound curve photographs of each individual Raga as sung or played by artists of recognised merit and then study its scale. This needs a lot of patient work and expenditure,

script and to the management and staff of the Arya-bhushan Press for their prompt and efficient service and uniform courtesy while the book went through the press.

I take this opportunity to express my sense of thankfulness to Shrimant Balasaheb Patwardhan, Yuwarāja of Miraj (Jr.)—who is himself an expert musician—for his sympathies and help in my past as well as present endeavour.

Last but not the least, I owe a deep debt of gratitude to Shrimant Narayanrao Babasaheb Ghorpade, Chief of Ichalkaranji, for his noble patronage to this book as well.

The author acknowledges his indebtedness to the University of Bombay for the substantial financial help it has granted towards the cost of publication of this book.

SANGLI.

Middle octave	C	D	E	F	G	A	B
Lower „	C_1	D_1	E_1	F_1	G_1	A_1	B_1
Higher „	c	d	e	f	g	a	b
Indian Notation	Sa,	Re,	Ga,	Ma,	Pa,	Dha,	Ni,

Addition of dashes at the top indicates still higher octaves and that below those still lower

Flats and double flats as — $D_\flat$ $D_{\flat\flat}$ $A_\flat$ $B_\flat$ etc

Sharps and double sharps as — $A_\sharp$, $F_{\sharp\sharp}$ etc

Septimal notes as — $7E_\flat$ $7b_\flat$ etc

Eleventh harmonic — 11 $F_{\sharp\sharp}$

Vibration number for the Middle C = 240

Index number for the frequencies of the several notes is placed at the bottom, as — $\begin{cases} C & D & E_\flat \\ 24, & 27, & 28\ 8 \text{ and so on} \end{cases}$

CONTENTS

CHAPTER I

A BRIEF SURVEY OF THE EVOLUTION OF INDIAN MUSIC

'Divine Truth, artistically represented to perception and feeling, forms the centre of the whole world of Art.' Truth however—as is often said—is half concealed and half revealed and hence needs closer acquaintance and association, before its full beauty is revealed The artist, in man, feels it, is inspired by it, and feels happy and elevated in conveying to others the golden touch of Art. When this process resolves itself into a well ordered and accomplished fact, Art makes over its conquests to Science and sets forth to explore unknown regions in the Land of the Beautiful

The development of Indian Music is not an exception to the above rule The cries' of the birds and the beasts—such as the cooing of the cuckoo or the neighing of the horse—were among the principal musical occurrences to catch the fancy of the early artist From such small and simple beginnings, music in India had grown into a well developed art, as far back as history can reach

In the Vedic period, the hymns were set to tune and rhythm and so there soon came into existence a class of singer priests The hymns needed accurate pronunciation and emphasis on particular syllables and words and extended over a fairly long duration of time. Their chanting, therefore, required great modulation of

voice and insertion of intermediate pauses Thus unconsciously, the essentials both of melody and rhythm came into prominence In the early stages, the melody was bound to be plain and curt Gradually, the limits were widened and it moved through a fairly large portion of the scale What was true of melody was equally true of rhythm From a simple accent and a pause, the rhythm developed into a science of evergrowing and varied cycles of time-keeping This resulted in a greater polish in the practice of the art and before long a Theory — rather a Grammar[8] — of music partly based on observed facts and partly on hypothetical pre possessions came into existence

The Vedic hymns were however too grave and rigid a subject for so plastic and subtle an art as music Eventually, music made a move towards the lighter side of life, and was more at ease with it, as it always has at its command a rare wealth of emotional appeal On this account, music has always been considered to be the fittest medium to express the joys and sorrows the languishing hopes and despairs and the thousand and one little vanities of the human race It is no wonder, therefore, if its field of activity soon shifted from the altar to the stage Thus there were performers for all occasions religious or festive There was already the singer priest who perhaps in course of time became the temple singer There was the tramp — as he is even today — who went round the country and entertained the country folk Lastly, there were reputed actors and actresses, who performed for the kings or for people of more urbane tastes

This really marked the beginning of a true and classical form of music. So, the popular practices of the earlier period were abandoned and several innovations were adopted, as the result of a close observation of the nature of musical sounds. The stage-opera of those days consisted of vocal as well as of a number of instrumental performers. Among the instruments, there were stringed instruments of many kinds—some to be directly plucked and played and others to be played with a bow. There were in addition, flutes, horns, cymbals and drums of many kinds. These facts clearly show that in those days, music was on the high road to advancement. The oldest and probably the first detailed exposition of the Theory of Indian Music belongs to this period. In the "Nātya Shāstra" or the Science of Dramaturgy, the sage Bharat (prior to 300 B. C.) gives a clear and detailed account of the Swaras—musical notes, of the Shrutīs—the microtonal intervals between the successive degrees of the scale, of the two Grāmās—parent scales, and of the Murchhanās—scales obtained by transposition. He has further given a detailed account of an experimental method[2] for deducing the Shruti-ratios. The method is rather crude, yet its merit lies in the fact that it is perfectly critical and truly scientific in spirit. We may, therefore, say that Bharat well and truly laid the foundations of the Physics of Indian music.

In his days, there were the two parent scales and in all, eighteen Jāties or fundamental harmonies. Fourteen of these were derived by mere transposition—seven from each parent scale — and the remaining four were obtained by a fusion of the two (parent scales). Thus all the

music was classified in eighteen broad groups or Jāties. Two songs widely differing in their melodic progression and æsthetic appeal were classed together, simply because the scale of each was derived from the same Jāti. A finer distinction was perhaps needed and so, in later years, each Jāti was further split up into or was replaced by what are now known as Rāgās. A Rāga has almost the same meaning as the term 'melody-type' in English, with the addition, however, that it is based upon melodic as well as æsthetic possibilities. The Rāgās came into being after Bharat and their coming marks a new era in the history of Indian music.

There is, however, no evidence which may accurately determine the commencement of this new period. The earliest and the most reliable reference to the Rāga-system is to be found in the Brahat-deshi of Matang (about 400 A.D.). In introducing the Rāga system he says that as the Rāga-way was neither explained nor referred to by Bharat and others, it was up to him to explain the same, in accordance with the practices then current[4]. This shows that the Rāga-system was already ripe and had developed well-respected standards, in the days of Matang. Not only the experts, but society as a whole, seems to have made due contribution to the formulation of new and popular Rāgās. It is for the detailed explanation of the 'popular system of music' that Matang wrote his epitome on music. In fact he names his book as Brahatdeshi, meaning 'A treatise on popular music'. By the word 'Deshi' he means the type of music sung or liked by men, women and children, as well as, by kings[5]. By the time of Matanga, not only

were the Jātics of Bharat replaced by the Rāgās, but the more orthodox types of the Rāgās also were further replaced by the new and popular types which evolved from day to day.

The Brahatdeshi largely draws upon the earlier works and particularly upon the Nātya Shāstra of Bharat, and mostly deals with the same topics, tho only addition being the chapters dealing with the Rāgās. But particular interest attaches to the fact, that the Rāga-idea had become sufficiently old and the old Rāgās were being replaced by new and popular ones. When and how the change took place is not told by Matanga, but the significant references to music, in old works of art, point to a very early date, indeed! As an illustration, it may be pointed out that an analysis of the works of Kālidāsa shows that the great poet closely followed the rules of art, as laid down in the Nātya-Shāstra[5] of Bharat. The frequent and significant use of musical terms and similies, the stage directions for singing particular verses only, and the propriety of time and melody of music to the occasion show that the poet was very well up in the science and art of music. Nay, he had indeed gone a step ahead of Bharat, for, Kālidas is found to have composed songs in one or two Rāgās. We can say this definitely, at least of one song[6], viz., that which the Natī sings in the prelude to the opening act of the Abhijñān-Shākuntalam. This song, as it appears, was to be sung in Sāranga[7] (Madhyamādi)—the very first Rāga of the renaissance period (or the period of the modern-Rāgās[8] later on referred to by Shārangdev, the author of the Sangita Ratnākar). This indicates that the musical

renaissance had begun as early as the times of Kālidās, if not earlier.

That the Rāga-system came into being in very old days is borne out by evidence from a still different quarter In the parody of a musician, which forms the subject matter of one of the fables in the famous 'Pancha tantra', (5th century A D), an ass poses as a great musician and in support of the fineness and delicacy of its performance, quotes the musical doctrine and further explains the Raga system The details about music given in this fable compare very favourably with those of the Northern school of Indian music, even of to-day.

The next authoritative work on music belongs to the early thirteenth century It is the famous Sangita Ratnakar of Shārangdev, who still inspires reverence in the minds of India's musicians He lived at the Court of the Yadav kings of Devagiri The Sangita Ratnakar deals at great length with music in all the three traditional aspects of it, viz, vocal and instrumental music and dancing Bharat had already dealt with these three aspects, in his Natya Shastra His music, however, had not developed any Ragas Matang wanted to describe instrumental music, in continuation of the general theory of (vocal) music, but unfortunately, further portions of his work are not yet unearthed But Matang gives a good account of the Raga system Shārangdev, the author of the Sangita Ratnakar, is more elaborate and scholarly in his treatment of the general doctrine of music, but does not in spirit differ

much, either from Bharat or Matang. In fact, he quotes them very often and appears to have closely followed the latter, in particular, in his arrangement of the several topics. Thus, he has devoted special chapters to instrumental music and dancing, in addition to those giving the general theory of vocal music. The treatment of vocal music in the Ratnākar is of course more exhaustive than that in the Brihatdeshi, but smacks of pedantry. For, Shārangdev tried to link the music of his days with that of the past, though at one place he frankly admits that the old type of music was altogether extinct. The Jāties of Bharat had disappeared by the time of Matang and the Rāgās had taken their place. These Rāgās again were replaced by fresh and new varieties, such as the Adhunāprasiddha[1] Rāgās of Shārangdev or those Rāgās well-known and current in his days. Under these circumstances, the most reasonable course, for Shārangdev, would have been to trace the growth of his Rāgās out of the older Rāgās, and the growth of these, in their turn, out of the Jātis or else to describe the Rāgās of his day, quite independently of the old forsaken practices of which,—there is ground to believe,—Shāraogdev himself had nothing beyond a vague idea. There is therefore a lot of controversy and confusion as to whether his music has anything in common with the present-day music, whether, of the North or of the South of India or if his system was altogether a different one. The later Pundits of both the schools, however, based their systems on that of the Ratnākar, in spite of the fact that these two schools differed widely in their practices. This made matters worse, indeed. A Pundit never stopped to think to

which school of music his art belonged and how different were the practices of his day from those of the ancient times, before he set himself to write an epitome on music What he did was merely to copy the old works and somehow fasten his own practices and beliefs on them. The music of Shārangdev is not therefore clearly understood in any part of the country and not even one of the Rāgās, elaborately described by him, has so far been successfully identified. The other portions of the Ratnākara, however, deal with the whole range of musical form and composition, and make the treatise a useful guide in many respects

Just after Shārangdev, i e, soon after the close of the thirteenth century, the Mohomedans invaded the Deccan and overthrew the dynasty of the Yādavās of Devagiri This had its own reactions on Indian music, as on other matters of culture Persian models began to be introduced into Indian music, evidently widening the gulf between the Northern and Southern schools. The Northern school later on adopted a new scale as its model or shuddha scale, while the Southern school retained the traditional one Scholars believe that this change in the Northern school was wholly due to our contact with the Persian art of which Amir Khushru was the pioneer. With his rare insight and art, he introduced new and finer variations of the Rāgās and invented new instruments It is, therefore, true that he not only contributed to the polish of the art but extended its possibilities also But, it is equally true that his attempts could not alter its traditional Hindu character Perhaps, he never attempted any

such alteration at all ! For, Amir Khushru himself says at one place —

"I am an Indian, if a Turk.
I do not derive my inspiration from Egypt
I do not therefore speak of Arabia,
My lyre responds to the Indian Theme

(*From the Life and Works of Amir Khushru by Dr Mohomed Vahid Mirza The University of the Punjab, 1935*)

Curiously enough, Amir Khushru is the inventor of a lyre, the famous Sitar of to-day The Shuddha scale of the Sitar is the same as the Shuddha scale of the Northern school and is believed to be a transposed form of the ancient Shuddha scale of the Veenā, of which the Sitar is but a modified form

If we take into consideration all the sharps and flats of the Sitar scale, then it happens to be a scale with twelve semi tones to an octave This scale gives the twelve identical notes, which the Southern Pundits use as the basis of their system The Sitar is thus a good compromise between the two schools, the major forms of the notes, giving the model scale of the North, and the minor forms giving the model scale of the South. Like the tempered scale of the West, it serves the needs of both the schools fairly satisfactorily Thus, it will be clear that the Sitar scale does not in the least suggest that Amir Khushru ever intended to effect any changes in the old Indian art, but on the other hand, strongly indicates that by inventing an ingenious instrument like the Sitar, Khushru helped to bring the two schools as near each other as possible

But the later theorists freely borrowed from the older works and added to the confusion already made by Sharangdev Most of them, however, were practical musicians of a high order and so the detailed information given by them about the practices current in their own days is certainly interesting and valuable Some of them really tried to systemise their views on rational lines, and among them, Pandit Ahobal, the author of the Sangit Parijāt (early 17th century) deserves special notice For, it is he who first gave the relation between (the pitch of) the different degrees of the scale in terms of the speaking length of a wire under constant tension[3] Ahobal may, therefore, be said to have taken a further step in the experimental development of the laws of Indian music

It is enough to say, here, that similar attempts were made by many Pundits almost till the end of the Mughal period But most of them belonged to the Southern school and there were only a few who described the traditions of the Northern school But even among the latter, there were none who started with the Shuddha scale as it was These, therefore merely reiterated in a more or less modified form what Ahobal had already said From this period onwards, we may say, the progress of the study of the science of music was checked, as the artists, pandering to the tastes of their masters, began to take all sorts of freedom with the orthodox Rāgas This caused the art to drift and created much disorder in its practice Yet, to this period (16th and 17th centuries A D) belong a few artists like Haridas, Tansen, Surdas Tulsidas Jagannath,

Sadārang and Adhārang, who, though innocent of the laws of musical sound, were great men of genius. Like, Palestrina (1524–1594 A. D.), they were guided in their paths by feeling, fancy and inspiration and have left an imperishable record behind them. They thus unconsciously laid down the foundations of what we call the classical style of to-day, which easily distinguishes the present-day music of the North, from that of the South.

Yet the distinct set-back given to science was so great and annoying, that by the time of the early British period, thinking people were thoroughly disgusted with the absurd classifications and meaningless conventions of the time. Thus, there were numerous Matās[10] or schools of musical traditions and lore, which hardly agreed with one another. One really wished for a simple yet a rational way out of the chaos. A step in the right direction was first taken by Mahārāja Pratāp-Singh-Dev of Jaipur (1779–1801 A.D.), who called a conference of the Pundits and experts of his day and in consultation with them got a standard work on Hindusthani music written. The Shuddha scale of this work Sangit-Sāra — appears to be Bilāwal, a fact worthy of notice. It was certainly a praiseworthy attempt, as it has preserved in writing the opinions of the best available experts of that period. This work, being of an anthological character, could not naturally offer the sort of a simple yet rational basis so eagerly desired for. The void was however soon filled up by the 'Naghamāte Āsafi' of Mohomed Reza (1813 A. D.). He boldly criticised all the four Matās or systems of

music, current in his days and pronounced them as wholly out of date and unsuited to the spirit and practice of his times and then gave his own Mata or system The central principle upon which he based his system was, that between every Rāga and its Rāginis, there must be close similarity or some common features The Shuddha scale of the Naghmāte Asaphi is again the Bilaval scale The book was written by the author after full consultation with the best artists of the day, and hence serves as a reliable guide to the music of his days

This leads us to the early British period During this period, music was confined to the Courts of the Indian Princes, but for whose genuine appreciation and noble patronage, it would have become almost extinct It is only in the latter part of the nineteenth century, that eminent Indian as well as English scholars took to its study Of the European scholars, most showed a peculiar want of imagination, in trying to solve the problem of Indian music, by a literal interpretation of ancient Indian works on music, combined with the use of mathematical tables[1] For, a literal interpretation of many passages leads one into a vicious circle of arguments Again, mathematical measurements of the distance between the frets of an instrument or of the length of a speaking wire on the Veenā, do not often represent the true length Playing on the Veena or any Indian instrument with strings, is largely a matter of guess work, for, a large number of the notes employed are obtained by increasing the tension of the wire, by pressing it hard with the finger and by

dragging it further on to one side. Under these circumstances, one cannot expect to find much about the Indian scales, by measuring the wire-lengths or the spaces between the frets of the different stringed instruments. Yet, this was the method employed by such workers as *Mr. Ellis* and *Mr. Hipkins*, in the verification of the Indian scales. The work of such scholars, though pursued on truly scientific lines, had but little practical value and in some cases, only helped to feed the fire of prejudice against Indian music, by providing a faulty standard of contrast between the Indian and European systems of music.

Among the Indian scholars may be mentioned the name of Raja S. M. Tagore (middle of the 19th century) who produced and patronised a number of works on Indian music. His Universal History of Music needs special mention, as it is a work of considerable value.

The Sangita Rāg-Kalpa-Drum of Krishnānand Vyās was published in Calcutta in 1842 A.D. Though it gives nothing new yet it has preserved a large collection of old songs. The industry and patience of the author who could bring out such a gigantic collection certainly command our admiration. The Gita-Sutra-Sāra (about 1867 A D) of Mr. Krishna Dhan Banerjee also needs special mention.

The Poona Gāyan Samāj also edited many books on Indian music. In more recent years notable contribution has been made by men like the late Pundit Vishnu Digambar. The Pundit gave us a system of

notation which is capable of recording old songs in a very faithful manner. The chief merit of the Pundit's work lies in the fact that he published whole songs, with all their progressions, embellishments and rhythmic variations and has thus left to posterity complete units of continuous and whole performances, as it were, of old classical songs.

Mr. Clements (I. C. S. Retired) and Mr. Deval of Sangli edited many books on music under the auspices of the Phil Harmonic Society of Western India. Their chief contribution to the study of Indian music lies in their research about the 'Intonation of Indian Music' and in their actual testing of many of the Rāga—scales, with the help of the Dichord They have also invented a simple form of staff notation, which can faithfully record any Indian song

Mr Clements and Mr. Fox Strangways deserve our thanks for yet another service which they have rendered to the cause of Indian music. Both of them are critics, gifted with rare insight and intelligence and by their able exposition of several musical topics have opened new avenues of critical and comparative standards of judging Indian music from the view-point of the Westerner

Last, but not the least, in the field, is the outstanding personality of the late Pundit Bhāthkhande of Bombay A truly modern man of a selfless spirit and well-equipped with talent and education, he saw that it was possible to establish the current Hindusthani Music System on a sound founda-

tion, so as to render its study easy and intelligible. He was able to do so by successfully applying the Mela-Kartā method of the Southern Pundit Vyankatmakhi, to the Northern system, without much sacrificing any of its specialities. As a result, he wrote a book in Sanskrit called 'Lakshya-Sangīta' and published it under a pseudo-nym. The book was written in the strains of the old Shāstric school and invited much adverse criticism, as Pundit Bhātkhande, in support of his statements elsewhere, freely quoted himself under the pseudo-nym. This was thought to be a great mistake on the Pundit's part and provided his adversaries much capital against him. But the book had its own merits. It gave in a very simple and compact form a practical basis for the Northern school of Indian music. The patterns for classifying the Rāgās were few and simple and as they were arrived at, by the selection of common features from similar or allied Rāgās, they easily confirmed with the current practices. As the book had a workable basis in view, the author rejected the critical method, assumed certain things and wrote it in the manner of the Nagha-Māte-Āsafi of the early nineteenth century. The book easily appealed to the student of music with the popular mentality, but the more critically minded thought that Pundit Bhātkhande in his zeal for compactness and patterns sacrificed facts to forms Pundit Bhātkhande, however, firmly believed in the utility of his method and thought that it would do more good than harm, to the study of Indian music. He, therefore, did not mind the criticism levelled against him and spared no pains in collecting, collating and editing old books and manuscripts on music. Simultaneously,

Musically there is n mass-awakening in modern India and demands for the inclusion of music in the University curriculum are repeatedly made in public meetings and Music Conferences. Under these circumstances, it is high time that the system of Indian music is subjected to critical nnalysis from the viewpoint of modern science. Such an analysis clearly discloscs that the system is hased not on caprice hut on broad scientific principles, which go n long way in building up the essential unities of Indian music. It is further possihle to show that the various æsthetic processes have their origin in these unities. Thus, without sacrificing any of its individual merits, it is possihle to base the system of Indian music on simple yet perfectly scientific foundations. It is with such a helief that tho present writer thinks it worth-while to place his humhle views in the matter, hefore all lovers and students of the Art and Science of Indian Music.

CHAPTER II.

The Nature and Limitations of the Function of Music and the laws of Musical Sound.

For an intelligent appreciation of the part played by music as an Art, it is necessary to know its place in the family of Arts and the nature and limitations of its function.

'Music is not an isolated Art. It forms a most necessary link in the great family of Arts. Its origin is to be looked for, at the same source as that of the other Arts. Its ideal functions are also the same.'

'Art in general is that magic instrumentality by means of which man's mind reveals to man's senses that mystery—'the Beautiful'.

In the realm of art, contact with the Beautiful is first established by drawing our attention to the close similarity between the beauties of Art and the beauties of Nature. The beauties of Nature are however the result of physical facts and are inseparable from their material cause. 'The beauties of Art, on the other hand, are an address to the inward mind and have an existence in the mental consciousness.' They are indeed beyond the reach of physical facts or pure nature and do not find a true, much less a full, expression in them. 'Art therefore seeks to find a true revelation and reality in itself.' It thus tries to transform the material world into an ideal world. Music, being the least material of

all the Arts, easily surpasses the rest in this respect and is therefore justly called the Art of all Arts.

But then, music is not altogether free to choose its own way. For, as it must necessarily employ the medium of sound for its expression, it must first obey the laws of musical sound, before being able to discharge its higher function as a pure art. Thus, Music is a dual entity—it is a science as a matter of exigency and is an art, by nature. As a science it has to obey certain physical laws, while as an art it creates its own forms and order, so as to make a direct appeal to man's æsthetic instincts and enrich him emotionally. Truly good music cannot therefore afford to sacrifice any of these aspects; the two are inseparable indeed! For, music without an appeal is a meaningless tyranny, however scientific it may be in its physical form, while a mere poetic call on the imagination has not the power to make the same direct and tender appeal, as when, it is accompanied by even a cursory melodic phrase. The processes which infuse artistic and emotional values in music form the æsthetics of music. Such values are often secured by the extension of the physical laws and in some cases by a deliberate departure from them. The reason for the departure is that the material unity of the Beautiful with the rigid physical structure is a narrower unity and soon ceases to keep pace with the highest Spirit of Art. The Spirit, therefore, breaks through the armour of the material form, disengages itself from its shackles and rises higher, reborn and radiant with the glory of resurrection—as it were. But, as will be seen later on, this occurs not in blunt defiance of the physi,

cal laws, hut rather as a continuation of the spirit for which these laws stand.

Thus, to understand *any* system of music and the technique of its several forms of expression, it is necessary to know these laws at the very outset, We may, therefore, give these physical laws first and postpone the consideration of the æsthetic principles to a later chapter.

To hegin with, music finds an expression only through the medium of sound.

Sound, which is musical, is pleasing to the ear while noise is distinctly jarring.

In a musical note, however attentively we may listen to it, we perceive no change or variation. The sensation is perfectly continuous and uniform.

A noise on the otherhand is the result of rapid irregular and distinctly perceptible alternations of various kinds of sounds, which crop up in a fitful manner.

Again, we may often come across a sound which is a mixture of the two.

A stretched string gives a perfectly musical sound. A beginner on the violin, however, produces a sound, in which the scratching of the how spoils the musical character of the note. Hence such a sound is a mixture, in which the element of noise preponderates.

The human voice can produce sounds of either class. In singing a sustained note it remains

quite steady, neither rising nor falling In conversation or reading, however, it perpetually varies in pitch A speech, wanting in such variations becomes monotonous

All musical sounds, whatever their origin, may be distinguished from each other, by three different qualities

Firstly, by the loudness or intensity

Secondly, by the pitch

Lastly, by the difference in the peculiar quality or timbre

For our purpose, we shall concern ourselves with the study, of musical sounds only, as the study of noises is meaningless

Loudness —Loudness depends in the first place on the greater or less energy by which the sound is produced Thus, when a stretched string is forcibly plucked, the sound is louder than when it is plucked or bowed lightly Again the note of a stretched string gradually becomes less and less loud and finally dies away altogether. In all such cases, the loudness is directly dependent upon the amplitude–which on its own part is dependent upon the energy which produces the sound and wears away with time

Next, it depends upon the nature and density of the medium, which transmits the sound

Lastly, the loudness depends upon the distance of the listener from the sounding body In an isotropic medium, it varies inversely as the square of the

cal laws, hut rather as a continuation of the spirit for which these laws stand

Thus, to understand *any* system of music and the technique of its several forms of expression, it is necessary to know these laws at the very outset, We may, therefore, give these physical laws first and postpone the consideration of the æsthetic principles to a later chapter

To hegin with music finds an expression only through the medium of sound

Sound, which is musical is pleasing to the ear while noise is distinctly jarring

In a musical note, however attentively we may listen to it, we perceive no change or variation The sensation is perfectly continuous and uniform

A noise on the otherhand is the result of rapid irregular and distinctly perceptible alternations of various kinds of sounds which crop up in a fitful manner

Again we may often come across a sound which is a mixture of the two

A stretched string gives a perfectly musical sound A beginner on the violin, however, produces a sound, in which the scratching of the bow spoils the musical cha racter of the note Hence such a sound is a mixture, in which the element of noise preponderates

The human voice can produce sounds of either class In singing a sustained note it remains

quite steady, neither rising nor falling. In conversation or reading, however, it perpetually varies in pitch. A speech, wanting in such variations becomes monotonous.

All musical sounds, whatever their origin, may be distinguished from each other, by three different qualities.

Firstly, by the loudness or intensity.

Secondly, by the pitch.

Lastly, by the difference in the peculiar quality or timbre.

For our purpose, we shall concern ourselves with the study, of musical sounds only, as the study of noises is meaningless.

Loudness:—Loudness depends in the first place on the greater or less energy by which the sound is produced. Thus, when a stretched string is forcibly plucked, the sound is louder than when it is plucked or bowed lightly. Again the note of a stretched string gradually becomes less and less loud and finally dies away altogether. In all such cases, the loudness is directly dependent upon the amplitude-which on its own part is dependent upon the energy which produces the sound and wears away with time.

Next, it depends upon the nature and density of the medium, which transmits the sound.

Lastly, the loudness depends upon the distance of the listener from the sounding body. In an isotropic medium, it varies inversely as the square of the

distance, so that, at double the distance, the loudness becomes four times less, at three times the distance, it becomes nine times less and so on

The above are the general laws about the loudness of sound Temporary variations can however be effected. For instance, the intensity of sound, confined to a tube, does not diminish even after a considerable distance and remains practically constant

Again, the note of a tuning fork mounted on a sounding board or a hollow box, is much louder than when it is not so mounted In this case the box is said to vibrate in a forced manner, along with the tuning fork The loudness however suffers very rapidly due to a greater rate of demand on the original energy, which now spends itself much sooner.

The proximity of bodies having the same natural period as the vibrating body is yet another factor which causes the reinforcement of the original sound This is a case of sympathetic vibration or resonance The bodies though not in any physical contact with the sounding body, on account of their having the same natural period, as the latter, pick up the excitement of their own accord—or as it is called, sympathet cally and reinforce the original sound

The second characteristic of a musical note is its ' Pitch It depends upon the number of vibrations, per second, of the sounding body

Pitch is independent of the amplitude of the vibration The pitch of a musical note, like the number of

vibrations of a pendulum, remains the same, irrespective of the gradual loss in amplitude.

It is found that the human ear can pick up sounds of frequency roughly between 20 to 38000 per second. The lower limit is mostly the same for all, but the upper limit may widely differ from individual to individual. All the notes between these limits are not however essentially musical.

Even for a rough musical effect, it is found that a note must have at least 30 vibrations per second, the upper limit being near about 4000. Though musical instruments are able to give any notes between these limits, for vocal performance such limits are brought still nearer, since the well-developed voice of a singer can embrace about three octaves at the best.

For a stretched string, under constant tension, the pitch varies inversely as the vibrating length.

Thus, if the length is halved, the pitch is doubled. If the length is made one-third, the pitch becomes three times as much, and so on.

Again, a string not only vibrates as a whole, but has several simultaneous modes of sectional vibrations also.

Thus, the note emitted by a string is a complex one and is built up of several tissues or pure notes, which happen to be the harmonic upper partials of the fundamental or of the lowest note.

The degree of prominence of any one or more of the upper partials depends upon how, where and with what force the string is excited.

The third characteristic of a musical note is the Timbre or Quality

It depends upon the mode of vibration and is governed by the relative prominence of the upper partials

The quality of the notes given by different instruments is not the same As musical instruments very widely differ in their material and make and in the mode of their excitement, there is a corresponding modification in the number of upper partials generated and in the degree of their prominence and hence in the quality of the note

Again, the notes of stringed instruments, alone, are rich in over tones which are true harmonic upper partials of the fundamental, whereas, those of bells and instruments with stretched membranes or of other non-stringed instruments are usually not so On this account, the note of a stringed instrument is richer in its musical quality than one of the same pitch given by the latter class of instruments and hence the preference given in music to stringed instruments

The pitch of a musical note can be found out with the siren or by other methods, but, in music, the actual number of vibrations is seldom wanted

Music judges two notes only by their relation or by the interval between them

The interval is the ratio between their vibration numbers

It is common experience that some intervals are consonant, while some are dissonant in effect.

The cause of dissonance between two notes is the generation of 'beats'.

Two notes of different frequencies create in a medium disturbances or waves of sound, such that these waves sometimes co-operate with and at times oppose each other, and the resultant disturbance is of an uneven character. This gives rise to the beats or the alternate throbbing sensation

The number of beats given by two notes is equal to the difference in their frequencies.

Very slow beats are not very unpleasant, but as the frequency of the beats increases, so does the unpleasantness, till for about 33 beats per second, it reaches a maximum. If the number of beats is still further increased the unpleasantness gradually diminishes,—the periodic and rapid beats themselves giving the impression of a new or a secondary musical note

We know that the note emitted by a stretched string is a complex note and contains in addition to the prime note, its harmonic upper partials These partials completely blend into the prime and are found to bear simple and determinate ratios towards it. Thus, beginning with the prime, the frequency ratios of the successive members of the harmonic upper partials' series may be represented by the series 1 2 3 4 5,6 7, etc Here then is the key to determine the conso-

Thus, it is clear that the nearer and more direct the harmonic relationship between two notes, the greater is the degree of consonance generated

Naturally, hetween two notes there will be such relations as those of absolute consonance, perfect consonance, imperfect consonance, imperfect dissonance, or perfect dissonance, etc It is not sufficient however to consider the case of the members of the upper harmonic series alone. For, though the early members of the harmonic series furnish hetween them all the consonant intervals upon which music is based, yet in practice, it is impossible to restrict music to such high notes The jump from the fundamental to the Octave is very great and requires the introduction of other consonant notes in this interval The study of the harmonic series offers here a good precedent In fact the consonant ratios, 2 3, 3 4, 4 5 etc, given by the first few harmonic partials may judiciously he used in introducing the required notes Thus a set of notes or a chord, to be mutually consonant, must employ some one from these ratios for tbc intervals hetween its individual members This simplifies the work of choosing consonant chords

To return to our point, in practical music, it is not enough to take into consideration, the relation between two notes only, inasmuch as melody or harmony invariably consist of more notes than two Thus, there would be chords of three, four or more notes A chord however usually means a chord of three notes, for, with the help of two such chords, it is possible to derive chords with four or more notes The two fundamental

CHAPTER III.

The Evolution of the Musical Scale

As already explained in the last chapter, consonant intervals make the passage from one note to another perfectly smooth and musical. Consonances have, therefore, always played a great part in all systems of music. It is true that to widen the range of choice and to put greater vigour and strength in the expression of the ideas, musicians do use, in addition, dissonant notes also, hut then, such notes are not allowed to last too long and at last are invariahly resolved into a consonanee.

A musical scale is a collection of such artistic steps, leading from the fundamental to its Octave. As the physical significance of the different eonsonances and dissonances was not at first truly known, it took a long time hefore scales hegan to ho constructed on really rational lines, as we now understand them.

The evolution of the scales has a great history behind it and its study simplifies the understanding of our modern scales and of many other practices connected with their construction. We shall therefore briefly traco this evolution, here.

To hegin with, in the musie of all nations, two unfailing characteristics are found ; rhythmic movement and proccdure by determinate degrees. To determine these degrees accurately is to construct a musical scale. From our knowledge of the harmonic series, we know,

that consonance and n simple law of formation supply between themselves the key to the rational construction of a musical scale But this knowledge of the harmonic series was the product of the later centuries, the consonant intervals known in the olden days being only the Octave and the Fifth As the Octave was n mere repetition of the prime, the Fifth alone was known to be a distinctly different yet a perfectly consonant interval So the early artists used to get additional notes by taking the direct or inverse fifth of the notes already known to them One by one fresh notes were introduced in the musical scale, until in Greece Pythagoras completed it

them indeed bear extremely complex ratios towards it. The interval $\frac{2^{56}}{3^{34}}$, repeating twice in the scale, is not at all simple Hence the Pythagorean scale of Fifths is essentially non harmonic in its character

In India, also, ever since the days of the sage Bharata (Prior to 300 B C) it was a well established practice to obtain the various notes of the scale by a chain of successive Fifths Though we cannot definitely make out what scale it was, yet it appears from the texts, that the scholars of those days were aware of the necessity of small corrections for reducing the complex character of some of the notes of such a scale of Fifths

Thus after five successive applications of the rule of a fifth, a drop of one Shrutee was thought necessary before a further application was to be made Such corrections were however based purely on æsthetic sense and we have no conclusive evidence to show that they were based on any definite physical principle

Further, in order to increase the musical resources, it was common both to Greece and India, to derive by transposition six new scales by making each of the remaining six degrees of the scale of Fifths, a fresh point of start for each successive scale

Let it however be remembered that the Pythagorean scale, as it was, could not satisfy the requirements of harmony Its Indian parallel also soon fell short of the requirements of melody even of those days The scale of pure Fifths, therefore, had its own day, but as time rolled on, had to give way to better ones. Another disadvantage of the scale of Fifths was, that

that consonance and a simple law of formation supply between themselves the key to the rational construction of a musical scale But this knowledge of the harmonic series was the product of the later centuries, the consonant intervals known in the olden days, being only the Octave and the Fifth As the Octave was a mere repetition of the prime, the Fifth alone was known to be a distinctly different yet a perfectly consonant interval So, the early artists used to get additional notes, by taking the direct or inverse fifth of the notes already known to them One by one, fresh notes were introduced in the musical scale, until in Greece, Pythagoras completed it

He constructed the whole diatonic scale from the following ' series of Fifths

$$F \pm C \pm G \pm D \pm A \pm E \pm B$$

Arranged as the successive degrees of a scale the series may be written as—

C D E F G A B c.

with the ratios —

$$1 \quad \frac{8}{9} \quad \frac{64}{81} \quad \frac{3}{4} \quad \frac{2}{3} \quad \frac{27}{40} \quad \frac{243}{512} \quad 2$$

towards the key note or fundamental C

The scale with intervals between the successive degrees might be written as —

C D E F G A B c

$$\frac{8}{9} \quad \frac{8}{9} \quad \frac{243}{256} \quad \frac{8}{9} \quad \frac{8}{9} \quad \frac{8}{9} \quad \frac{243}{256}$$

Here, though the law of formation of the scale is very simple the individual notes have nevertheless, an origin very distant from the fundamental note and some of

on account of unequal nnd complex intervals, transposition without introducing large errors was not possible. The same was true of the derived scales also. So, it was thought advisahle to distrihute the interval between the prime note and its Octave, equally among twelve notes. This is the Tempered Scale, so named, because it tempers or slightly alters the character of the notes of the ideal scale. The successive notes of the Tempered Seale form a perfect Geometrical Progression and are separated from their neighhours hy the same common interval—the mean semi-tone. The tempered scale has a simple law of formation and offers n special faculty to fixed-toned instruments, of change of hase at will, without changing the intermediate intervals. But, with the exeeption of the fundamental and the Octave, no other notes of the Tempered Scale are truly consonant and the melodies given hy these are never perfect—much less perfect are the harmonies. As the music played to eqnal temperament is hound to be nlways a little out of tune, it soon hecomes insipid.

In Indian music also, one octave used to he divided into twenty-two Sbrutees or microtonal intervals. Bharat expounds the whole Shrutee-theory in about ten lines and Shārangdev describes it in ahout fourteen curt couplets. The literal interpretation of these passages leads one to think that the Shrutee intervals must be all equal and uniform. Accordingly, tbe Shrutee-scale would he a tempered scale, having twenty-two instead of twelve equal intervals in one octave. As the distribution happens to be made among about doublo the number of notes, the error is bound to he smaller

than that in the Tempered Scale Hence the principal degrees of the Shrutee-scale are a nearer approach to the notes of the ideally harmonic scale Being a tempered scale, however, it has the same drawbacks as the Tempered scale of the West and cannot therefore take the place of an ideally perfect scale

The Shrutee interval may be easily calculated in the following manner Let r be the common interval between the successive notes of the Shrutee-scale. Then the interval between the fundamental and the Octave is made up by twenty two intermediate Shrutees or common intervals

$$\text{Thus} \quad \frac{\text{Octave}}{\text{Fundamental}} = \frac{2}{1} = r^{22}$$

$$r = \text{one Shrutee} = 2^{\frac{1}{22}}$$

Thus, if we want to find the number of Shrutees in a given interval and if x be taken as that number, then x is given by the equation

$$2^{\frac{x}{22}} = \text{The given interval (of a Fifth Fourth or a Third etc)}$$

The following table gives a comparison of the calculated number of Shrutees, making up the different intervals, with the number as given by the ancient Indian books on music and clearly shows where and how the Shrutee-scale differs from the mathematically expected scale.

Interval	Mathematically derived value of x (the no of Shrutees) in the interval	Values assigned by the ancient Indian writers
Octave	22	22
Fifth	12 86	13
Fourth	9 14	9
Major Third	7 08	7
Minor Third	5 78	6
Major Tone	3 72	4
Minor Tone	3 36	3
Just Semitone	2 06	2

At this stage, it is desirable to know the other side of the Shrutee scale controversy, which has provided the bone of contention for ages and has set one great man against another even to this day

Both Bharat and Shārangdev assigned a proper name to each Shrutee and both put them into five broad Jāties or classes[1] It is on account of this classification of Shrutees, that some critics think that with Bharat or Shārangdev, all Shrutees were not equal and that there were sharps and double sharps, flats and double flats even among the Shrutees, the middle one being the normal interval Nobody who cares to read these old books can deny the grouping of the Shrutees in five classes The real disagreement, however, is

themselves miserable by catching at this thing and that and by twisting and perverting the plain meaning of words. Their wish that the old ideas be granted as the correct and scientifically true ideas is certainly pious, but is not in keeping with the plain facts of history. The better way would have been to keep the mind open and have the frankness of correcting the old ideas, wherever necessary. This would have saved a lot of time and labour wasted fruitlessly till now. As an instance, it is funny to see how the ten lines of Bharat or fourteen couplets of Shārangdev have been the source of unending discussions which, length for length, may far outweigh the information of all the encyclopædias of the world put together!

But, as it was, even within the scale of Fifths various methods of execution were possible. Other scales, like the ancient modes, were generated by the fundamental scale and had equal claims to attention and stood on a level with the original scale. Thus both in Greece and India, the modal scales also were frequently used.

In Europe, however, the requirements of harmonic music later on reacted in a peculiar manner on the construction of scales and as a result only one of the old tonal modes (the Major mode of today) remained unaltered, while the rest, after undergoing several modifications, fused into the so-called Minor mode. These are the two scales—the Major mode and the Minor mode, which form the backbone of the music of the West.

The closest and the simplest relation of the tones is reached in the Major mode, as all its notes are but constituents of the compound tone of the tonic or its Fifth, above or below.

The Major mode is really built up of three Major chords.

					3←	3	←3		
Notes.	C	D	E	F	G	A	B	c	(d)
Index No.	24	27	30	32	36	40	45	48	54
of frequency.	1	→	1	→	1				
					2	→	2	→	2

The first Major chord is indicated by I, the second by 2 and the last by 3. The arrow supplied to the figures indicates the point of start and direction of application in each case. Similarly, the Minor scale consists of three Minor chords.

					3←	3	←3		
Notes.	C	D	E♭	F	G	A♭	B♭	c	(d)
Index No.	24	27	28·8	32	36	38·4	43·2	48	54
of frequency.	1	→	1	→	1				
					2	→	2	→	2

It should be remembered that in both these scales, the principle of tonality is fully observed, as all the tones are connected by a simple relationship to the chief note, the tonic, as also between themselves.

Similarly, if a particular scale is put forward as the Shuddha or the natural scale of Indian Music, one ought to show that such a scale is the result of truly scientific practices and does not rest on mere caprice. The Shrutee-scale—as put forward by its present-day

exponents—cannot satisfy this expectation, as one is not sure if the Veenā of today is exactly like the Veenā of the ancient days Even if it were so, the other difficulty is that the passages dealing with the Shrutee-scale lend to various interpretations and hence the result is not conclusive Further, the mere measurement of the position of frets on a Veena or Sitar cannot completely determine the nature of the scale, as the Veena-notes are seldom the free or open notes of the string, but are invariably such as are obtained by slight variations in pressure, effected by 'Meend or a push here and a stretch there

Under these circumstances some are tempted to adopt the Major Scale of the West directly as the model scale of Indian Music But such a step is too bold and moreover unnecessary, as it is possible to trace the evolution of the scales of Indian Music out of a simple but a very important practice, common to both the ancient and modern systems of Indian music This practice is none other than the 'employment of a drone as a necessary background for all music and enables us to determine fully the tonality of Indian music As it however forms the primal unity of Indian music, it needs more critical consideration and may on that account be allowed to form the subject matter of a separate chapter

CHAPTER IV

From Speech and Recitation to Folk-Music

and

From Folk-Music to the Classical Stage.

So far, we have concerned ourselves only with the Physics of music. We may however do well to remind ourselves at this stage that tradition, inheritance and association also have always played an important part in the development of all known systems of music. Incidentally, the Rāgās, the melodies and the various methods of progression of Indian music are the outcome of the efforts of many generations and what we call classical music to-day is the very cream of such an age-long musical activity. It will now be our aim to investigate the characteristic features of each stage of the progress of Indian music, so as to have a consistent and connected view of its evolution as a whole.

Speech, recitation, verse, folk songs and songs of the classical type are apparently the gradual stages in the development of musical form. These forms evidently fall into two groups: the one not requiring any musical accompaniment and the other requiring it as a matter of necessity. Thus speech does not require any musical accompaniment at all. Recitation and verse, as also the simple folk songs seldom employ an accompaniment, and even when accompanied are poetic rather than musical in effect.

hard sounds and to restore a sense of ease and completeness, a speaker introduces cadences in his speech, although unconsciously. This is why cadences are markedly prominent in languages in which a large number of hard consonants figure actively. For instance, the Kannada (Canarese) language, in which hard consonants occur on a very large scale, abounds in cadences. Thus, in everyday conversation or speech in that language, a singsong-better a semi-musical-tone asserts itself prominently at the closing of a sentence. This is true not only of the Kannada language but is equally true—although to a much smaller extent—of such languages as the Sanskrit, in which compound consonants occur very frequently. In the pronunciation of words with such compound consonants, the vowels are invariably lengthened, primarily, for making the syllables perfectly clear and audible, yet secondarily, for reducing the harsh character of the speech to a minimum. The lengthening effect is particularly noticeable at the closing of a sentence, as such closing is tantamount to the completion of a statement. The sense of ease or completion is secured by what we call the introduction of a cadence The effect becomes still more pleasant or musical if the words are set to rhythm. This is easily done by a happy sequence of the long and short vowels occurring in the words It is further heightened by fixing the length or duration of each sentence or line, –that is to say–by securing the balance between the several sentences of the speech.

Thus to make ordinary speech, smooth, mellow and well-balanced in point of rhythm, cadences must

be well distributed and must recur at regular places or intervals This means the union or adaptation of spoken words to orderly and rhythmic periods or in other words to metrical forms–or the rendering of prose into poetry This explains why the recitative of ancient plays always embraced one metre or the other The metrical compositions are therefore the most ancient types of musical form and must have evidently served as models for the later types, particularly for the popular tunes or folk songs

Folk music is the music of the masses When common people sing a song, they know nothing about the intervals used in it To them the intervals occur naturally But then, folk music is not the music of a savage, as some are apt to think On the otherhand, it is an integral and living part of any musical culture worth the name and has held its own in spite of the great developments in classical music

Folk music has its own charms and even among the illiterate masses, a large number of people are found to possess a fine ear for such music and occasionally, a rare facility of performance also The study of folk music claims one s attention all the more as it has many things in common with the classical form of music Thus in many of the classical Ragas, one is often reminded of similar groups of notes or melodies forming some popular tune or folk song But it is important to remember here that there is a fundamental difference in the processes and the consequent effect of the two types of music For, though the notes and melodies of folk music are similar to those of classical

music, folk-music never gives an impression of a particular Rāga or classical mode as such and yet gives its own stamp, which eludes all the established criteria of the Rāga-system of classical music A study of the details of this individual stamp of folk-music may help us in our constructive view of the evolution of Indian music as a whole and may indirectly throw some light on the causes, which give a different stamp to classical music

With such a belief, the present writer undertook a study of Folk music, as it obtains in Mahārāshtra and published his results some four years back in the 'Bhārateeya Sangeeta —(a bimonthly magazine of Indian Music that used to be published at Poona Vol III No 2 of 1935) Beginning with the singsong way of reading, recitation of Mantras or hymns, the different ways of reciting metrical or other types of verse and other similar compositions, the present writer analysed the folk songs proper The results obtained were further found to be true with respect to similar compositions in all the principal languages of the Sanskrita stock This is as it should have been, for, such languages have many things in common, particularly the prosody and the modes of poetic improvisation The results were found to be true even in the case of specimens from the Kannada, although that language is not of the Sanskrita stock. In each case, indigenous reciters were requested to recite the different pieces of poetry and folk songs in the most natural or non academical manner and then an analysis of the notes, melodies and other particulars of such recitation was made The major findings of this study may be briefly given in the following pages

1 In folk-music, the recitation of music is always coupled to the time-span of the poetic words making up the metre and there are no tonal extensions as such

2 The melody, though flowing on freely, is often pivoted on a particular note or group of notes and circles round such a note or notes

3 The melodies of folk-music are very simple and employ a few notes at a time They seldom move in two tetrachords at a stretch

4 In the elementary forms folk-music does not employ a drone, yet there is a level always maintained to which the music invariably returns so much so that not for a moment is the sense of this level or tone either lost or weakened

5 The *maximum* number of notes employed in folk-music is *nine* These consist of the seven consonant notes viz those of the Major scale and two more viz the Minor Third and Minor Seventh

6 The minor forms do not however occur as frequently as the major ones

7 Sometimes the *enharmonic* forms of the same note occur—the higher form occurring in the ascent and the lower one in the descent

8 Prayer or other religious hymns or songs when chanted alone to oneself employ only one note—the tonic—and are literally monotonous

9. If recited in public, they employ one or two more neighbouring notes, the whole recitation never extending beyond one tetrachord.

10. For a very big audience the voice is often raised by a Fourth or Fifth, but even then the melody seldom extends beyond one tetrachord at a stretch.

11. The alternative way of recitation for a big audience is to begin on the higher Octave and proceed by a descending melodic progression.

12. In the longer metres and songs the melody has necessarily to be lengthened in duration and hence it embraces notes from two tetrachords. But there is usually an imitation in one tetrachord of what occurs in the other.

13. The melody is so simple yet sure, that the intervals and their sequence is correctly observed in a natural way and needs no previous thought or special effort. Students of classical music know how difficult it is to take a leap of a just Fourth or Fifth, but in Folk-music such leaps are correctly taken even by a lay reciter, without any conscious preparation or effort.

14. A piece of poetry or a song always contains an even number of lines or divisions. At the end of every odd line, there is felt a sense of incompleteness; the sense of completeness returning only at the end of the next even line.

15. This incompleteness is of the character of a query or interrogation Its immediate cause is that the odd line does not end on the tonic, but ends on a harmonically more distant note, usually the next higher note—the Major Second So a deliberate shift from the tonic at a psychological moment when it is strongly in demand, causes perturbation or gives a shock, which we call incompleteness

At the close of the next even line, however, there is a well planned return to the tonic, and this at once restores ease and the sense of completeness

16 No single note receives any individual prominence either by way of duration or stress The notes are mere counterpoints—as it were—to *the order of long and short syllables which* make the metre As such, the notes of Folk music are never of the sustained type and hence scarcely afford an opportunity to bring out the beauties of any harmonic relationship of the several notes, either towards the tonic or even between themselves

17 The nine notes of Folk music are almost the same as the nine principal consonances, which chiefly figure in fixing up the tonality of classical music (See—Chapter V) Thus, it appears that even in the folk stage, there were no cultural reactions, which opposed the formation of a truly natural and hence of a harmonic scale

18. In the more strict forms of the metres—viz. the Gana—Vrittās, rhythm is regulated by particular Gaṅās or groups of syllables and hence by a particular order and quantity of syllables. In the lighter forms however, i. e. in the Mātrā-Vrittās, it is regulated by a periodic accent and hence not by quantity but by regular stress.

19. As will be seen from its scales, melodies and rhythm, Folk-music does not violate the laws of the Physics of music even once, but in spite of its perfectly scientific structure, is unable to stir our emotions through the power of tones alone. The reason for this is, that Folk-music has a Science but no Art behind it. Just as water is neutral in colour and takes the tinge of the colour we add to it, Folk music has no tonal moods of its own, but adopts the mood poetry brings to bear upon it. Thus the same metre, with the same melody, may without any harm be used to convey sentiments of diametrically opposite characters.

20. In folk-songs proper, the poetic theme is never very serious, nor the language very high. A simple, domestic or worldly topic—often the celebration of a marriage or love between young men and women, or an adventure or some such incident supplies the theme. The narrative also is never very serious or straight. An opportunity is frequently sought for a touch of drollery or odd humour, which is often the

the blowing is made more vigorous. It is on this account that the cries of birds rise or fall by the intervals of the harmonic series alone and so their constituents are mutually consonant. If the same considerations are extended to the human voice, it is clear that it should have a natural preference for generating consonant intervals, if it is to preserve the greatest possible ease and quality. Be it, therefore, the ear or the voice, for the best possible musical effect, the excitement of either must in no way be forced or strained but must be truly sympathetic or natural. *Musical effect and ease of execution therefore go hand in hand.* Thus the scale for the folk-songs is supplied by the major scale or by some one of its transposed forms. There are four such forms which are generally met with. They correspond to the Ionian, Aeolian, Dorian and Lydian harmonies of the Greeks. According to Mr. Clements, 'a study of European and ancient Greek music shows that these scales are essential ingredients in any evolved form of music'. It therefore appears that in almost all countries, the folk-songs employ simple rational scales, though the music of such songs may mean nothing more than a musical way of pronouncing or reciting the individual words. In such songs, there is of course no tonal progression, as such, independently of the words. The advanced folk-songs also are mostly plain and simple in point of their tonal structure. But such songs, when accompanied by a drone and executed with tonal flourishes or occasional embellishments put on a semi-classical appearance, and lead us to the very door by which songs of the other group—

i. e. those of the classical type—make their appearance on the scene.

To this second group, which necessarily requires musical accompaniment, belong the semi-classical and classical songs, proper. Advanced Folk-songs and Dances are of the semi-classical type, whereas the 'Chamber-Music' of today represents the classical form of music.

A consideration of the musical potentialities of the accompaniment employed by each form may easily bring to one's notice the salient features of each type and thereby further simplify our present investigation.

In Indian music, the accompanying instruments are intended to discharge one or more of the following functions:—

1. To supply the keynote or the tonic, in the form of a drone etc.
2. To accompany or imitate the vocal or other principal parts of music, in a point to point or symphonic manner.
3. To supply the rhythm.

The drone supplies the keynote and maintains the level or the pitch of the song and thus ensures the accuracy of the intervals used. It thus provides an easy means of judging the degree of consonance of the several notes forming the melody, by throwing them into direct contrast with the constituents of the harmony, built up by the several upper partials of its primes. For a rich musical effect of such a nature, stringed

instruments alone can be used; for, it is well known that instruments of the drum-type and the like are comparatively poor in effect and without recurring excitement, are unable to supply any sense like that of a drone. Such instruments produce higher partials, which are inharmonic and are therefore jarring. In short, for supplying a drone or the Tonic-Key as a back-ground, instruments of the drum or bell-type are not useful. Stringed instruments and the like, alone, serve the purpose well.

For the discharge of the second function viz. a point to point accompaniment or symphony, the stringed instruments and those of the reed type alone are useful for the reasons given above.

For the third function viz. supplying the rhythm, instruments of the drum-type, though poor in point of richness of tone or musical quality, offer a special advantage. The recurring excitement of such instruments and the rapid variations in the intensity of their sound, confer on music the element of motion and power. Thus skilful drumming can produce almost every shade of motion and of delicacy or power. The drum-type of instruments are therefore useful in making music as much powerful and emotional, as is desired.

Now, Folk-music and particularly Folk-dances employ a variety of instruments like drums, bells, cymbals, horns and trumpets and employ-if at all- a very weak and poor type of a drone-supplied either by a reed pipe or by the Tuntunē or the Ektār-the latter two being coarse instruments with one string

only The rhythmic element is therefore very powerful in such songs and dances, and as for the melodic effect, it is totally drowned by the tangled mass of sounds produced by the drums and such other instruments The emotion is supplied not so much by the consonant or dissonant character of the notes used, as by the theme of the song It is further strengthened by the gesticulations and bodily movements of the performers and its rise and *fall* is *regulated* by appropriate variations in the drumming In such music, 'all are performers, no audience, and the crowd is a stimulus that keeps everyone dancing and howling in emulation' Thus one or two give the song and others follow them, by repeating the same lines once again All join together, when the lines lead to the burden of the song As the voices are usually untrained and shrill, the effect is not at all musical but is only manly or powerful It is further heightened by the *quaint* dresses of the performers and by the outdoor environments, in which such songs and dances are usually performed In the more vigorous types such as the War Dances, the music is accompanied by the waving of flags and fire brands and by the brandishing of daggers and swords and as a consequence, becomes very powerful and awe inspiring The songs accompanying such dances do not employ any fixed or regular scale but freely employ discords and effect sudden changes both in the loudness and pitch of the sound Thus at one time a song may be very rough, shrill and powerful, at another it may suddenly become soft and tender with corresponding changes in the manner of the drumming also This state of things is to be seen

particularly in the Powādās or the War songs of the Mahrāthās and other similar songs

There is yet another type of Folk songs, which appears almost classical. In this type the accompaniment is richer and the drums etc employed are also tuned to the tonic note Such songs are usually a mixture of the Folk and Classical ways of performing music and only serve as a link between the two There is however nothing that is fundamentally new or different about them and hence they need not detain us any longer

The last and by far the most important group is of songs of the classical type In this group there are three different ways of performing the music, which may be either vocal, instrumental or of the nature of a dance These three types together constitute what is traditionally known as 'Sangeeta Among these, voice is man's first instrument in time and value Other instruments merely imitate the voice, but cannot produce the articulate effect, which voice alone can produce It is true that in harmonic music, instruments play an important role and hence stand on a par with the vocal parts, but as Indian music has no harmony, there is very little scope for the instrumental parts as such They have always a secondary place in the scheme and merely follow or imitate vocal music In dancing also, the vocal part forms the chief centre of interest which is further enhanced by appropriate acting and delicate bodily movements In Classical music, therefore, paramount interest attaches to vocal music only This is why theorists from the ancient

times down to this day, have always taken the word 'Sangeeta' to mean vocal music, in particular

In vocal music of the Classical type, there are two broad groups– (1) Chamber music and (2) Mass music.

Chamber music is of the solo type and requires a harmonically rich accompaniment, usually in the form of a drone The mass of tone is therefore never very powerful and accompanied, as it is, by a mild but harmonically rich accompaniment, the effect is never oppressive, but is always sweet and tender Such music, therefore– be it gay or sad – is invariably of a reflective and intellectual character.

In the other variety, to which belong the Harikathā or Bhajan parties, and the Bajantries or Indian Band-parties, more drums and cymbals and almost none of the stringed instruments are employed Hence such music develops a large mass of tone and becomes powerful, but is less reflective and intellectual In classical songs proper, the ethos or the emotional effect depends, not so much upon the theme or the rhythm, as in the case of the Folk-Dances, as on the consonances and dissonances forming the melodic law or the scale

In short, the music of Folk-Songs and Dances, though poor in point of harmonic effect, is powerful and virile and the seat of the power is in the large mass of sound and in the enchanting rhythm of the accompanying instruments of the drum-type

As for the advanced Folk songs and songs of the Classical type proper, they are very rich in point of the harmonic effect and as they employ stringed in-

struments in preference to those of the drum-type are, though less vigorous, more sweet and touching than the Folk-songs proper. On this account, the Indian system has always restricted its attention to the consideration of the melodic and harmonic relationship between notes and the interpretation of their æsthetic value. Hence, in India, the science of music means the science of classical music only. In fact, the harmonically poor forms of music have really no science of their own. Ignorance or imperfect knowledge of the acoustic laws, poor and faulty accompaniment and want of fineness of performance are usually responsible for the poor musical effect of the early forms of music. With growing understanding and knowledge of the acoustic laws, music has always evolved a higher form. Thus, from speech evolved recitation and verse, from recitation and verse, the folk-songs, and from the folksongs, songs of the Classical type. It is then apparent, that a study of the science of Classical music may provide a rational basis for explaining and understanding the development of the entire structure of music, both Classical and Non-classical. Consequently, there is no further necessity of extending our investigation beyond considering the essential features and processes of Classical Indian music alone.

CHAPTER V

The Unities of Indian Music

Classical music picks up the thread where Folk-music leaves it In Folk music there is no conscious aim of understanding the musical meaning of tones, much less of extending it further for artistic effect The evolution of Folk Music is inherently a process of an unconscious synthesis of musical material both good and bad Classical music, on the other hand, leaves nothing to chance, makes a conscious effort of isolating the good material from the bad and always aims at an intellectual understanding and interpretation of such material for further artistic effect When such material is subjected to a conscious analytical process, it becomes evident that the various musical elements and operations hinge upon certain physical laws of broad and universal nature These laws therefore play an important part in building up the Unities governing the different Musical Systems Further, even under the same Unity, numerous ways of musical expression are possible e g by creating different orders in the use of the musical material and form This is how the different kinds of musical forms and expression have come into being

We shall now briefly explain the Unities of Classical Indian Music and describe the particular forms and orders, which each one of them develops in a subsequent chapter

There are three principal Unities which govern Indian Music. They are.—

1. The performance of all music, to the accompaniment of a drone.
2. The strict adherence of the music to a particular Rāga or melodic law.
3. The strict and correct observance of a chosen measure of time throughout a given piece of music.

The First Unity :— 'The primal unity of Indian music is in the tonic or the drone. The reference of all music to the accompaniment of a drone is a practice which is common to both the ancient and modern systems of Indian music. The drone establishes a strong feeling for tonality, by supplying the sense of comparison or contrast of the different notes of a musical piece, with the constituents of its harmony as a whole. As the tuning of the prime notes of the drone is essentially the same to-day as it was in the old days, we can, without perversion of any ancient doctrines and traditions, make the drone a starting point for fully determining the tonality of Indian music. To enable the reader to appreciate the part played by the drone in Indian music, it is desirable to consider here how a feeling for tonality at all asserts itself and what the forms of tonal relationship are.

It is common experience that a melodic phrase or a chord appears to be the chord of a determinate root, even though there may be no accompaniment. It is because the ear unconsciously analyses the compound

tone into its partials This process of analysis does not however become a subject of conscious perception To make it so, the chord must be accompanied by the root note, which then functions as a tonic To make the analysis easy and perfectly perceptible, the accompanying note must be sustained as such sustained notes draw the attention of the singer towards the beats and help him to check his own voice in the most decisive manner so as to avoid any dissonance Thus the principle of tonality first comes into prominence unconsciously and finally asserts itself boldly

Tonal relationship is of two kinds–*direct* and *indirect*

Two tones are said to be *directly* related when a perceptible partial of one coincides with a similar partial of the other

Thus the intervals C G F are *directly* related to the note C

The relationship is *indirect* when the two notes happen to be the upper partials of a third note taken as auxiliary For example –

$$\underbrace{c \quad d}_{G} \qquad \underbrace{A - B}_{E} \qquad \underbrace{B\flat - c}_{F}$$

The pair of notes above each bracket though not *directly* related between themselves are *indirectly* related through the corresponding bottom note, as they respectively happen to be the Major Fourth and Major Fifth of that note The bottom note therefore serves as an auxiliary and is invariably included in the Tonic-Key or the drone so as to make this relationship easily perceptible The Tonic-Key of Indian music is the drone

of the Tamburā and serves as a point of departure by means of which the pitch of the song can be maintained and the accuracy of the intervals, ensured The drone is usually of two types–the G-type and the F-type. The reason why these two notes are chosen as auxiliary notes in preference to other notes will be clear from the following explanation

In making the choice for an auxiliary note, the Fifth and the Fourth of a note have a claim which is next to that of the Octave only. The Octave, however, is not a new note and only reiterates what the fundamental claims for itself Of the remaining notes, the relationship of the Fifth and its inversion the Fourth to the fundamental is the closest and as such has been acknowledged in all known systems of music Thus the closest and the simplest relation of the tones is reached when they happen to be the constituents of the compound tone of the tonic or of the Fifth, below or above it The interval of a Fifth is therefore one, which secures the closest and the simplest relation between two tones In *addition to* the fundamental the drone should therefore include both its Fourth and the Fifth But though each of them is individually related to the fundamental as a consonance they happen to be so near each other, that their compound tone gives strong beats The drone therefore includes only one of them at a time The absence or omission of the other is not however appreciably felt, as it being a strongly consonant note the ear grasps or conceives its presence in a subjective manner. As a consequence, the drone is split up into two parts viz the G-type and the F-type Really speaking, they

are not two different types as such, they are in fact the complements of a single ideal Tonic Key or harmony. Under the circumstances, each complement may appear to fall a little short of the ideal harmony, but as already explained, the deficiency is almost completely wiped off by the peculiar habit of the human ear, to follow or grasp the presence of strongly consonant intervals in a subjective manner. The Fifth being a more consonant interval than the Fourth, there is less deficiency in the drone of the G-type than in that of the F one-and hence less strain in following or imagining the existence of the complementary part It is on this account that Indian music uses the G-type of the drone for almost all the Rāgās, and the other type for a few Rāgās only But whether the drone is of the G-type or of the F-type, the method of admission of new notes to the scale is common to both The new notes may be admitted either through their relationship with the Fifth or with the Fourth. In simpler Rāgās, the relationship is usually restricted to one of these, but as will be seen from an analysis of the scales of some complex Rāgās, the principle has a wider application and is applied in its dual form, to form the scale of one and the same Rāga

As an illustration, it may be stated that if there is a relation of a Fifth between the corresponding notes of the two tetrachords of a scale, then there is automatically a relation of a Fourth, between the corresponding members of its first tetrachord and those of the tetrachord just below it (i e from the lower octave), and those of its second tetrachord and those of the tetrachord just above it, (i. e from the

higher octave). Thus let us take the two tetrachords of the middle octave of the so-called Shuddha scale of Indian music and reproduce that scale over one tetrachord on either side

1st tetrachord of the higher octave			
C	D	E	F
480	540	600	640

1st				2nd Middle octave			
C	D	E	F	G	A	B	c
240	270	300	320	360	405	450	480

2nd tetrachord of the lower octave			
G	A	B	C
180	202 5	225	240

Then the sequence of relationship of the notes C and G is CG in the first two tetrachords of the middle octave, and GC elsewhere Similarly the sequence of relationship of the other notes also is reversed, if the series begins one tetrachord below or above the middle C. Thus means that there is an alternate relationship of a Fourth and a Fifth, taking place between the two successive tetrachords of any given scale, reproduced, if necessary, both ways This is true particularly of Indian music as it uses three consecutive octaves, meaning that the range of an Indian song or musical composition happens to be from four to six successive tetrachords

In practical music, the instrument Tamburā supplies the drone The Tambura has a big gourd at the bottom, with a long hollow wooden neck above It has two bridges, one at the centre of the flat side of the gourd and the other almost at the top of the wooden neck—the distance between the two being

usually about three feet or a little more Four wires are stretched across the bridges and their tension is varied by working l ttle pegs at the top of the wooden neck The two m ddle wires are of steel and are tuned in unison, to any desired p tch The two outer wires are of brass The first of them is a little thicker than the two middle wires and is tuned to a Fifth or a Fourth below the standard or the fundamental note g ven by the two middle wires The other outer wire-the fourth and the last in the group—is th cker even than the first wire itself It is tuned just an Octave below the fundamental note The drone is of the G or F-type according as the first wire is tuned to a major Fifth or Fourth in the octave below the fundamental note

The drone therefore is not a single note but is a collection or a bundle of several harmonic tissues in the form of upper partials and the combination notes in addition to the primes In such a combination the primes of course predominate in point of intensity and duration and of the primes the note of the two middle w res in part cular, as it serves as the base for the secondary note G or F as the case may be The drone is thus a harmony built up by the primes their upper partials and the consequent combination notes generated

Whenever a p ece of music is given to the accom pan ment of such a drone a comparison or contrast of the notes occurring in it with the constituents of the harmony of the drone is unavo dable Such notes alone as happen to have the nearest *direct* relationsh p with the constituents of the harmony of the drone,

will compare favourably with it or will be felt as consonances and others for want of any such relationship will receive no backing and will provide a contrast and sound as dissonances due to the generation of beats. A rational consideration of the constituents of the harmony of the drone is therefore bound to give all the fundamental consonances of Indian music and may further help us in ascertaining how far the principle of tonality is followed in the construction of its different scales.

The drone is made up of three classes of notes, (1) The primes, (2) The upper partials of the primes, (3) the combination notes

Among these, the prime notes are the most conspicuous of all and inherently dominate the others in the harmony as a whole

The next group is that of the upper partials of the primes

As is well known, partials higher than the sixth are scarcely audible and so there is no practical necessity of considering the upper partials series beyond the sixth partial Normally, such partials may not be audible in the drone, but when they are employed by artists, the ordinarily thin partials may, by virtue of their union with similar but more powerful notes produced by the artist, gather some force as to strongly influence the judgment of a listener. To provide some basis for judgment even in such extreme cases, we may consider the upper partials' series up to the ninth partial.

Thus, for example, the Western musicians stop at the seventh harmonic, as they find it extremely unsuitable for the purposes of their system It is however not so with Indian music The Indian professional singer not only uses the septimal intervals often, but uses them with distinct advantage and then the result is peculiarly soft and tender According to Mr Clements 'the importance attached to the septimal intervals i e those derived from the seventh harmonic, places the music of India in the first rank of intellectual developments of musical art'

The eighth partial is a mere repetition of the prime.

The ninth partial when reduced to the middle octave is just a major tone higher than the primo note and is a Fifth of the Fifth of the prime note It is then through the Major Fifth acting as an auxiliary note, that the ninth partial establishes its relationship towards the tonic note

The tenth is but a repetition of the fifth partial

It is from the eleventh partial onwards that we first come across notes, which, when not a repetition of any of the earlier partials become more and more complex in their relationship towards the fundamental

In short, the first six partials alone, being audible, deserve our full consideration, the next three viz from the seventh to the ninth inclusive, though not audible in the drone, may sometimes gather some little strength and hence need some consideration, whereas, of the remaining higher ones, some are mere repetitions of the earlier ones and the rest, not being

either audible or closely related to the tonic, do not invite any consideration at all.

We may therefore consider the upper partials' series of the primes of each type of the drone, up to the ninth partial in general and sixth partial in particular.

The harmonic upper partials' series for the G-type of the drone is as given below:-

Ordinal No. of the partial:-	1	2	3	4	5	6	7	8	9
Prime note.									
C	C	c	g	c′	e′	g′	7b′♭	c″	d″
C_1	C_1	C	G	c	e	g	7b♭	c′	d′
G_1	G_1	G	d	g	b	d′	7f♭	g′	a′♯

From the above series, it is clear that the order of the audible consonances is as C, G, c, d, (b) and among the inaudibles $7b_\flat$ is more prominent than either $7f_\flat$ or $a_\sharp$.

The series for the F-type of the drone may similarly be written as :-

Ordinal No. of the partial:-	1	2	3	4	5	6	7	8	9
Prime note.									
C	C	c	g	c′	e′	g′	7b′♭	c″	d″
C_1	C_1	C	G	c	e	g	7b♭	c′	d′
F_1	F_1	F	c	f	a	c′	7e′♭	f′	g′

The order of the audible consonances in this group is as C, G, F, e, (a) and among the inaudibles $7b_\flat$ is more prominent than $7e_\flat$ or d''.

We shall now consider the combination notes. Of these, there are two varieties:—(1) Difference notes and (2) Summation notes. The frequency of the

difference note is equal to the difference of the frequencies of the two original notes The frequency of the summation note is equal to the sum of the frequencies of the original notes

The combination notes are again of the first, second or any higher order according as they are generated by the prime notes or by the first, second or higher partials of one note with similar partials of the other The degree of loudness or prominence becomes less and less as the partial happens to be higher and higher

Let us now find out the combination notes that may arise between the primes of the drone

In the G-type of the drone, the notes are –

G_1 (18) C (24) and C_1 (12)

So the first difference notes will be —

$C - G_1$	$G_1 - C_1$	$C - C_1$
24 - 18	18 - 12	24 - 12
C_{11}	C_{11}	C_1
6	6	12

The first difference note in all the three cases is the fundamental note itself, only one or two octaves below Hence, it only strengthens the effect of the fundamental note

The second difference notes are —

$2C - G_1 = E$)	$2G_1 - C = C_1$)	$2C_1 - G_1 = C_{11}$)
48 - 18 = 30)	36 - 24 = 12)	24 - 18 = 6)
$2G_1 - C_1 = C$)	$2C - C_1 = G$)	$2C_1 - C$=unison)
36 - 12 = 24)	48 - 12 = 36)	24 - 24 = 0)

Thus the second difference notes also are not new notes at all They already belong to the partials series of the primes themselves

If we persist in taking the third and higher difference notes, the resulting notes turn out to be the members of the upper partials series of the *smallest common difference*, which in our case is C_{11} (6) and serves as the root note of the series given by the difference notes Thus it will be seen that the difference notes of any order do not generate any new note, but only strengthen the effect of the primes themselves and their upper partials

The summation notes again, for the same notes viz G_1 (18), C (24) and C_1 (12) will be —

$2G_1 + C = e$)	$2C + C_1 = e$)	$2C_1 + G_1 = 7B\flat$)
$36 + 24 = 60$)	$48 + 12 = 60$)	$24 + 18 = 42$)
$G_1 + 2C = 11f\sharp$)	$C + 2C_1 = e$)	$C_1 + 2G_1 = e$)
$18 + 48 = 66$)	$24 + 24 = 48$)	$12 + 36 = 48$)

Summation notes of any higher order will also be represented by multiples of 6 and hence will belong to the series of the partials of which the number 6 represents the root note Thus the summation notes also do not generate any new notes other than those already belonging to the upper partials series of the primes or of their difference notes Hence all the three groups of notes strengthen the earlier members of the upper partials series including the seventh partial $7B\flat$

Thus in the G-type of the drone, the prominent consonances when arranged in a descending degree of consonance will be —

C G E D B 7B♭, the first four being already audible in the drone

If we extend a similar consideration to the F-type of the drone, the following scheme gives the difference and summation notes for that type

1st difference notes —

$C - F_1 = F_{11}$) $C - C_1 = C_0$) $F_1 - C = F_{111}$
$24 - 16 = 8$) $24 - 12 = 12$) $16 - 12 = 4$

As the number 4 happens to be the *highest common factor* of the series, two of the difference notes are but repetitions of the prime note F_1 only one and two octaves below and the third difference note is a repetition of the other prime note C Thus the difference notes are members of a series of upper partials of which the root note is represented by F_{111} (4) The same will be the case for the second or any higher order of difference notes

As for the summation notes, those of the first order will be –

$F_1 + C = A$ $C + C = G$ $C_1 + F_1 = 7E♭$
$16 + 24 = 40$, $24 + 12 = 36$ $12 + 16 = 28$

The notes of the second order will be —

$2F_1 + C = d$ $2C + C_1 = e$ $2C_1 + F = A$
$32 + 24 = 56$, $48 + 12 = 60$ $24 + 16 = 40$

$F_1 + 2C = f$ $C + 2C_1 = c$ $C_1 + 2F_1 = 11B♭$
$16 + 48 = 64$ $24 + 24 = 48$ $12 + 32 = 44$

Similarly any higher order of summation notes will give such notes as happen to be the members of the upper partials series of which the note F_{111} represented by the figure 4 will act as the root note

Thus either the difference or summation notes of any order do not generate any new notes in the Γ-type of the drone also, but further stress the early members of the upper partials' series for the primes The prominent consonances, when arranged in a descending degree of prominence will then be C G Γ E A of which the first four members are audible in the drone The notes C G and E being distinctly audible and common to both the types of the drone, serve as good links between the notes of the two types

In short, the combination notes do not materially alter the effect of the upper partials' series for the two types, but on the other hand strengthen the first five terms of the series concerned and lend some stress to the seventh harmonic also The complete series of the G-type up to the first nine members may be written in the middle octave as—

C D E 7F♭ G A♯ 7B♭ B c (1)

Similarly the series of the F-type, written in the octave F_1-F is—

Γ_1 G_1 A_1 B_1 C D 7E♭ E Γ...(2)

or in the octave C-c is,

C D 7E♭ E Γ G A B c (3)

the reason for writing the second series in the octave F_1-F is that the note F_1 serves as the root note for the combination notes of that type and in the series for the upper partials of the primes also, it is strongly backed up against the tonic note C

The corresponding notes of the series (1) are a just Fifth above those of the series (2) Hence the

Major Fifth. Thus the pairs, C–G, D–A♯, E–B, F–c are related by an interval of a just Fifth.

If we choose the septimal intervals, then C D ♭E F G A♯ ♭B c is also a scale with similar tetrachords of which the corresponding notes are related by the relation of a perfect Fifth only. These two are the fundamentally consonant scales, possible under the circumstances. Additional scales, may be derived by admitting notes which, though not directly related with the primes, may claim an indirect relationship with them through the notes of the fundamentally consonant scales. Such relationship must be either of a Fifth or a Fourth. (The following table gives such derived consonances—reduced to the middle octave—with their relation to the fundamentally consonant notes:-

Note of reference.			The derived notes:-			
			Fourth		Fifth.	
1.	C	(240)	F	(320)	G	(360)
2.	D	(270)	G	(360)	A♯	(405)
3.	E	(300)	A	(400)	B	(450)
4.	F	(320)	B♭♭	(426⅔)	c	(480)
5.	G	(360)	C	(240)	D	(270)
6.	A	(400)	D♭	(266.6)	E	(300)
7.	A♯	(405)	D	(270)	E♯	(303.75)
8.	B♭	(432)	E♭	(288)	F*	(324)
9.	B	(450)	E	(300)	F♯	(337.5)
10.	E♭	(288)	A♭	(384)	B♭	(432)
11.	F♯	(337.5)	B	(450)	D♭♭♭	(253.125)
12.	A♭	(384)	D♭♭	(256)	E♭	(288)
13.	D♭♭	(256)	F♯♯♯	(341⅓)	A♭	(384)

Apparently every new note obtained may be taken as a new base and the series may be continued indefinitely But it should be noted that such derived notes become more and more distantly related to the primes and soon cease to be consonant in character. From these additional notes, fresh scales may be derived on the model of the fundamental consonant scale The following are the most common scales, of such a type, in which the two tetrachords are perfectly symmetrical and are related by the relation of a Fifth or a Fourth, and in which both the auxiliary notes F and G are necessarily included Hence these scales serve as the essential or model scales for those of the chromatic type

1 Notes C D E F G A♯ B c
Frequency 240,270,300,320,360,405,450,480
The two tetrachords here are related by a Fifth

2 Notes C D E F G A B♭♭ c
Frequency 240,270,300,320,360,400,426⅔,480
The relation is that of a Fourth

3 Notes C D E♭ F G A♯ B♭ c

The relation is that of a Fifth

An analysis of the various scales used in Indian music shows that it uses scales both of the consonant and chromatic types. (See appendix for the chromatic scales). As Indian music has no harmony, chromatic scales do not offer much difficulty in their use. What the system insists upon is that it must keep in tact the relationship of a major Fifth or major Fourth, between the corresponding members of the two tetrachords. To keep this relationship always true and prominent, the system further requires every scale to include, in addition to the fundamental note, either its major Fourth or major Fifth so as to function as the consonant note for reference in the second tetrachord. Thus in each tetrachord the music starts from and necessarily returns to the prime notes of the drone. This helps the performer to maintain his sense of tonality firmly. The other consonances generated by the harmony of the drone serve him well in fixing his intermediate notes also, as they provide in themselves a good standard of comparison and contrast. The whole question of choosing a scale, then, reduces to introducing notes in a given tetrachord and then by the principle of parallel tonality, the notes of the other tetrachord are automatically fixed. Such notes, as happen to be the members of the harmony of the drone, will give consonant scales and others will give less consonant or dissonant scales. To heighten the effect, the dissonances may in certain cases be made further acute. In such cases, the scales are of course chromatic, but help to widen the range of artistic performance.

In practical music, the method of the vocal performer fundamentally differs from that of the instru-

mentalist in obtaining any scales. The instrumentalist sticks up to his frets or keys and thereby often exposes himself to small errors. The vocal performer on the other hand bases his judgment on the harmony generated by the drone, and so his sense of tonality is never lost. Thus if a sharp or a flat of a note is wanted, the instrumentalist will change the position of his frets or vary the tension a little. The vocal performer on the other hand will try to link up such a note, with one of the prominent consonances of the harmony of the drone, either as a consonance or as a dissonance, according as the case may require, and thus always observe the true interval, by the simple device of the accompaniment of a drone as a constant background to his music.

Again for a change in scale, the instrument player has to make a new adjustment for every new scale, but, for the vocal performer who uses a drone, there is no necessity of any new arrangement at all; all scales whether with sharps or flats can be fully brought out with the help of the same common harmony of the drone. The constant use of the drone trains the performer in the habit of employing truly harmonic intervals and in the proper understanding of the artistic use of dissonances. The drone further strengthens the modal effect and enlarges the scope for variation between Rāgās belonging to the same family. Above all, it boldly asserts the feeling for tonality, by constantly stressing the tonal relationship between the individual notes on the one hand and the fundamental or the tonic note on the other. Since there is no harmony as such, in Indian music, 'the notes of a chosen scale stand out from each

other as clearly as the faces of our friends do to our minds eye', and their individual consonant or dissonant character also stands out clearly and prominently on account of the contrast provided by the harmony of the drone In Indian music, particular interest therefore attaches to the tonal relationship of each note-be it a consonant or dissonant one-towards the harmony of the drone, of which the fundamental or tonic note is the chief and powerful constituent The First Unity of Indian music therefore is in the correct observance of the tonal relationship of the chosen notes, and it is easily and correctly observed by the constant reference of *all* music to *the accompaniment of a drone*, as previously described

It is on account of the increasing influence of the drone, that the whole system began to be considered as being based on one Grāma (a group of essential notes) instead of on two, as in the old days Really speaking in today's music there is no one parent mode or Grāma as such, but it is a harmony of several consonances which is provided by the drone that has taken its place Again this harmony contains such intervals as may admit of a relation of a fourth or a fifth between the corresponding members of the resulting or chosen scales It is therefore wrong to suppose that the whole music has been reduced to one Grama — the Shadja Grāma The fact is that music has been using intervals belonging to both Grāmās and other intervals also, which do not belong to either of them, and after due incorporation of the merits of each, has extended its possibilities much beyond the limited field of the Grāmās With the constant use of a drone, it is impossible to ignore

the strong sense of tonality which the music develops and that over and above the relation of the individual notes towards each other, the relation of each note towards the tonic or the key note asserts itself boldly and throws its relation with the other notes in the back ground It is on this account, that scales began to be judged by their reference to the tonic note Again, as the G-type of the drone is used on a very large scale, —for almost all kinds of music-and the F-type in a few cases only, the consonances belonging to the G-type largely engaged one s attention But there are many musical compositions, which though played or sung to the G-type of the drone, employ consonances of the F-type This means that the linking of tones is a matter of a free choice and has its roots in the essential laws of harmony, rather than in the narrow and unintelligible relations of the old Gramic scales Following what Sir James Jeans observes at one place, we may say that this is in keeping with the natural tendency of continually enlarging the potentialities of the scale The scale has been in turn pentatonic heptatonic, of twelve or twenty two notes and may yet be split up into a larger number of divisions, in order to make it still richer and more accommodative But in every such attempt the simple ratios of the harmonic upper partials must beyond doubt figure most prominently The Indian system is not an exception to the above Originally the scales were very rigid, then they went by tetrachords, then there was the thought of symmetry in the two tetrachords, then they went by *sangatees* or by associating two particular notes together and finally the construction of a scale

now rests on the relationship of the different notes towards the harmony of the drone or the Tonic-Chord of Indian Music, if we may call it so. In Western music, a strong feeling for tonality makes the passage from a major to a minor scale easy and enjoyable. In Indian music also there is a similar development. Thus in the scales of certain Rāgās, there is a frequent change from the relationship of a Fourth to that of a Fifth and *vice versa* and under the circumstances the scale evidently develops the *enharmonic* forms in the case of some of its notes. It is the drone therefore and the consequent feeling for tonality it creates, that make such music easy and enjoyable. On this account, the reference of all music to the constant accompaniment of a drone forms the first and foremost Unity of Indian music.

CHAPTER VI

THE UNITIES – CONTINUED

Raga, the Second Unity of Indian Music.

The observance of a strict melodic law or a *Raga* throughout a piece of music is the second important Unity of Classical Indian music In a Raga, a particular scale is chosen and its notes are so arranged as to excite a certain emotion in the mind of the listener Raga is a distinctive feature of Indian music and is not known to the music system of the West in which *Harmony predominates and the mood changes* according to the impulse of the moment

The word Raga literally means 'that which enraptures the hearer Incidentally, it is not a plain, simple thing It is neither a scale nor a mode much less is it a melody for, a single scale or a mode may generate more Ragas than one and in one and the same Raga *innumerable melodic arrangements are possible* Thus in the ancient days there were only Jātis or modes but as it was later on found that it was possible to extend the potentialities of a mode still further the modes were gradually replaced by what are called Rāgas Out of a single mode or a particular scale, many different Ragas can be formed by giving prominence to this or that particular note or to a particular melodic nucleus A Raga is thus an artistic idea or an esthetic scheme of which a scale a mode and a melody or melodies form the raw material

There are three chief categories under which the Rāgās are classified. Thus a Rāga is Shuddha or pure, Chhāyālaga or derived or is Sankeerṇa, – meaning – of mixed origin, according as the scale employed by it, is Shuddha or pure, derived–meaning, slightly modified–, or is wholly chromatic in its character. The Shuddha Rāgās admit of a more general and broad treatment than the Chhāyālaga, in which the treatment becomes more and more specific, till finally in the Sankeerna Rāgās it becomes absolutely singular.

Again, in one and the same category, there are three primary ways in which a single scale may be employed for the formation of the Rāgās. Thus, if only five degrees of the scale are chosen, the Rāga is Odawa or pentatonic, if six are chosen, it is Shādava or hexatonic, and if all the seven are chosen, it is Sampoorṇa or one employing the full scale.

Further, there will be Rāgās, which may be Odawa both in ascent and descent or may be Odawa in ascent only and Shādava or Sampoorna in descent. Thus for the Odawa variety alone, there will be three sub-varieties possible and for the three main varieties together, there will be nine sub–varieties of choosing the notes for ascent and descent from one and the same scale. A Rāga must therefore, belong to one of these nine varieties in wlich a scale can be chosen.

The chosen scale does not however attain the status of a Rāga, unless it further obeys the following conditions:—

1. It must necessarily possess æsthetic potentialities.

2 It must employ the full range of an octave and so must cover both the tetra-chords

3 It must not omit both Γ (Ma) and G (Pa) simultaneously, meaning, that it must always include at least one of them, if not both

4 It must not take both flats and sharps of the same note consecutively

It may be shown that the above conditions have a truly scientific origin in the principle of tonality itself as explained in the last chapter and have nothing that may be called capricious about them Let us therefore examine their significance one by one

Thus the æsthetic potentialities, necessary for a Rāga, according to the first condition, are realised by giving prominence to a particular note in preference to others This preference throws that note in direct contrast with the Tonic-harmony of the drone and thereby boldly upholds the particular consonant or dissonant character of that note, thus imparting a distinct æsthetic stamp or ethos to the Raga The note receiving such prominence is called the Vadi To heighten the effect of the Vadi, another note either its fifth or fourth —and hence belonging to the other tetrachord is given next best prominence This note is called Samvadi or the helpmate of the Vadi The Samvadi imitates what the Vadi does in its own tetrachord and being at a distance of a Major Fifth or Fourth from the Vadi helps by providing a point of reference to maintain the accuracy of the intervals between the notes of its own tetrachord It thus bears an equally consonant or dissonant

relation towards the base note of its tetrachord, as the Vādi bears towards the tonic, which acts as the base note of the first tetrachord. If the Vādi belongs to the second tetrachord and the Samvādi to the first, the comparison still holds good but with the bases interchanged i. e. of the Samvādi with the tonic and of the Vādi with the base-note of the second tetrachord. In any case there is a symmetry between the corresponding intervals of the two tetrachords of the scale of a Rāga. Thus the principle of similarity of the two tetrachords of a scale, as required by the *First Unity* is facilitated by the Vādi-Samvādi arrangement which as a result requires the observance of the second condition viz. that a Rāga must cover both the tetrachords fully.

The æsthetic potentialities of a Rāga are further extended by assigning to it, particular combinations of the principal notes of the chosen scale, certain embellishments, ascending or descending, conjuct or disjunct forms of melodic motion, and the hour of the day appropriate to the mood or æsthetic stamp given by the Vādi and Samvādi of the Rāga. All these however come under the *Æsthetics* of music and will therefore be dealt with, in a separate chapter.

Now, the third condition viz. that a Rāga must not omit (Sā) C, or the tonic and must include at least (Ma) F or (Pa) G, evidently shows that each of the two tetrachords of a Rāga must begin *invariably* with its respective base note. The base notes are none other than the prime notes of the Tonic-harmony of the drone. Thus the arrangement of the tetrachords of a Rāga—scale is directly based upon the practice of

tuning the Tambura which supplies the drone 'without which the Rāga scale would be like a ship without a rudder' This explains why a Raga must include either Ma (F) or Pa (G) in addition to the tonic note Sā (C) and also why Indian music requires the constant accompaniment of a drone

The last condition that a Rāga must not take the sharps and flats of the same note consecutively has also a similar justification For, while passing from the fundamental to its Octave by gradually raising the pitch of a note, it is at certain specific points only, that consonances come to a peak The degrees of the Shuddha or modal scale are so chosen as to represent the consonances, indicating these peaks Thus between two consecutive peaks or notes of the model scale, there can be no other peak or note, as consonant as the two Shuddha notes An intermediate note, if chosen, is bound to be a little more sharp or flat than the natural notes A Shuddha or a natural note being a consonance compares more favourably with the drone, as also with its neighbouring Shuddha notes, than either its sharp or flat form The Shuddha note is therefore related to the drone and other Shuddha notes as a consonance and the sharp or the flat one as a dissonance In taking the Shuddha note consecutively with its sharp or flat, there will thus be two conflicting æsthetic processes in one and the same Raga and so they would baffle the very unity for which a Rāga stands viz that of making a specific emotional or æsthetic appeal

In such a procedure, there is yet another difficulty viz that small chromatic intervals not belonging to the scale check the easy flow of melody and are a dis-

tinct handicap particularly in vocal performance, and produce dissonance. Again, introducing discords, without any æsthetic end in view, is meaningless and merely annoying. For all these reasons the consecutive use of a sharp or flat of a note along with its Shuddha form is strictly forbidden in Indian music.

Over and above these rules, there are some other conventions, which a Rāga has to observe. These are an outcome of age-long associations and practice and have assumed almost the same significance as the scientific rules.

A few of the more important conventions may be given here.

Thus particular Rāgās are to be sung in particular seasons and even in that season, at a particular time of the day or night. It would be considered a sacrilege to sing a Rāga at any other time, except the one assigned to it. The restriction about the season has almost disappeared in course of time, but the restriction about the time of the day or night still dies hard.

For the purposes of the allotment of proper time to each, the Rāgās are divided into Purva and Uttar Rāgās The Purva Rāgās have their Vādi note in the first tetrachord, while the Uttar Rāgās have their Vādi in the second.

In the Purva Rāgās, as the Vādi belongs to the lower part of the scale, it is but natural that they should have a tendency for ascending progression, while on account of the high position of the Vādi, the Uttar Rāgās can evidently show their best charms in the

descending form of progression. The Purva Rāgās are sung from midday onwards up to midnight and their ascending progression is in keeping with the more vigorous and active part of the day. The Uttar Rāgās on the other hand, with their descending progression, are delicate and plaintive in character and justly employ those *hours, viz. those from midnight* onwards up to midday — during which one is mostly by oneself and puts on a reflective mood. Except perhaps the psychological reason given above, there is no other reason which gives a satisfactory explanation of the particular order of allotting particular hours to the different Rāgās.

Sunrise and sunset happen to be the *respective* midpoints of the two-time cycles and it is at these times that the best Rāgās of each type are to be heard. Such Rāgās are called Sandhiprakāsh meaning twilight Rāgās, and are the most favourite of the artists and listeners alike. In Indian music, it has been customary to associate specific Rāgās with specific emotions. Why a particular emotion is associated with a particular Rāga is a matter which needs closer consideration. As such, the problem is dealt with independently in another chapter and there it will be seen that it has a truly scientific basis. But, as far as the average student of Indian music or the professional is concerned, his ideas about the relation between the Rāgās and their Rasās or emotions are more or less arbitrary and are often queer or exotic.

So far, we have given the general principles and conventions of the Rāga-system. But it need not be

supposed that the system is perfectly rigid and incapable of further changes or evolution, as some orthodox scholars and almost all professionals believe. In fact it may be seen that the Rāga-system has been an ever-growing idea and has gradually developed along rational lines of evolution, even in the past. Thus from scales, modes or Jāties were obtained. From the Jāties, Rāgās were obtained by particular arrangement of the tetrachords and by giving prominence to an individual note or group of notes serving as the Rāgānga or nucleus of the Rāga. In the early stages, the nucleus was as far as possible so chosen as not to disturb the symmetry of the two tetrachords. But, as there was bound to be a very limited number of scales with perfectly similar tetrachords, the Rāga system had to employ scales with dissimilar tetrachords also. In such scales the parallelism between the Vādi and the Samvādi could not remain in tact and the Samvādi began to be neglected. In such cases the Rāga criterion began to be based upon the Vādi aided by special Sangatees or associations of certain notes together- a process almost similar to the progression of Western music by chords. But as the constant reference of all music to the drone could further offer free scope for every note of the Rāga to assert its individual character, either as a consonance or a dissonance independently of the other notes of the Rāga scale, the Rāga criterion settled down solidly upon giving prominence to a desired consonance or dissonance and hence to a particular note of the Rāga scale, and so manipulated the other notes as not to be prominent enough to efface the effect of the chief note – the Vādi or the dominant. To preserve

the individual character of the Rāgi, it was necessary to refer it always to the Tonic harmony of the drone and as such, the drone itself became the point of start and return of all music The drone thus superceded the old convention of the Graha and the Nyās- viz of beginning music with a specific note and ending it with another specific one This is quite justifiable in a system employing a drone, which supplies the very basis for judging the several notes employed in a Raga.

But although the drone was a simple and rational means of fixing the tonality of music, the very fact, that it needed no conscious effort on the part of the performer to fix it, deprived the majority of the performers of the art of tuning The state of things was not so bad, when the music was accompanied by such instruments as the Beena But this set up the Beena-kārs who well knew the art of instrumentation, against the vocal performers who badly needed it, but never cared to know it This rivalry brought about a permanent separation between the vocal and instrumental performers This happened about the close of the Seventeenth century and from that time the vocal performers relied solely upon their æsthetic sense for the development of their art and as was natural, many of them could not have the necessary fineness of æsthetic judgment So, music began to take liberties with the laws of harmony and developed along chromatic lines But as the drone was a strong and sure bond between music and harmony, only such chromatic deviations, as were really interesting or served an æsthetic purpose survived and others perished as a

matter of course. This is how some of the Rāgās with chromatic scales have come into being.

This tendency of taking undue freedom with the Rāgās has been rampant among the present-day professionals and the so-called music-directors, who having discarded the use of the Tonic-harmony of the drone, instead prefer the harmonium. These, therefore, stand the least chance of developing the faculty of correct intonation. It is true that people are becoming more musically-minded on account of the wide field opened to music by the Phonograph, the Radio and the Talkies, but it is equally true that the æsthetic sense of the masses cannot at once attain the degree of fineness, which a cultured mind may need or possess. Under the circumstances, the performers have been vying with one another in supplying music, as bad and rough as is in demand! Of course, there are honourable exceptions and it augurs well that thinking people have been sick of such music. Further it is a welcome sign of the times that the number of people taking an academical interest in the study of Indian music is increasing everyday. One may therefore hope to see that music is soon freed from the clutches of the present-day music-caterer.

No account of the Rāga-system will be considered as complete, without an attempt to distinguish clearly the Rāga-system of the North from that of the South. The necessity arises from the fact that the two systems had originally a common ancestry.

According to the Pundits, the Southern system remains mostly what it was. It is the Northern system

which has changed, perhaps due to the change in the æsthetic bearings such as the greater predominance of the drone or perhaps on account of the bifurcation of instrumental music from the vocal The change must have occurred partly as a matter of evolution and partly on account of the reactions of its contact with the Persian or Mohomedan art

The Raga system of the South is a matter of mathematical computation and is thus easy to understand The Southern system recognises only twelve notes in an octave This number includes all the notes, the Shuddha, as well as the sharps and the flats also Each tetrachord consists of six notes Of the twelve notes a Raga scale is to employ only seven notes covering up the whole octave and has to obey further all the rules previously referred to in this chapter

Thus by different arrangements of the notes of each tetrachord and combining them so as to give the maximum number of individually different scales, thirty six scales are obtained for Ragas which take the Shuddha Ma or the note F and an equal number further for those that take the tivra Ma or the note F♯ in all giving 72 Thātās or parent scales Again each Thāt or parent scale gives 484 different Rāgas by permuting the notes of each of the nine varieties of choice, such as the Odawa Shadava and Sampurna etc Thus the total number of the possible Rāgās according to the Southern system is $72 \times 484 = 34848$ But, of these, only about two hundred are current even in the South, the rest of the lot, as one may easily imagine, are either not explored or do not possess æsthetic individuality

necessary for the formation of a new Rāga, as distinctly different from any already known. By no means of course, the Rāga-system has been fully explored, nor is it ever possible to do so, but the fact that the number of Rāgās with individual æsthetic potentialities is itself very small, is at the bottom of why only a few Rāgās are current and shall remain current even in the South.

The Northern school on the other hand did not attempt the mathematically possible but æsthetically impossible task of obtaining the maximum number of Rāgās, but chose to start with such scales as offered a good æsthetic nucleus. In the old days as previously referred to in the first chapter, there were rival Matās or schools of musical thought. Each, however, proposed six as the minimum number of primary Rāga-scales. These were the six Janak Rāgās or the parent-scales of the Northern system. Each Janak Rāga, had five Rāginees (or wives) which were derived by shifting the choice for the Vādi from one note of the scale to another. Again each Rāginee, by either including some fresh notes or by omitting some from its original ones, was to give six sons or subsidiary Rāgās. Thus the total number of Rāgās and Rāginees for one Janaka Rāga or parent-scale was thirty-six and for all the six parent-scales together 216. This is about the same number as is current in the Northern system of to-day. Of course, no single artist knows all these Rāgās, nor even the best among them are able to give more than hundred to hundred and fifty of them. The reason for this small number is that Rāgās, differing only by a small change here or there, nearly merge into one another and lose their individuality as such. It is in this manner that a

majority of the mathematically possible number of Rāgās overlap each other and lose their individual significance. Thus the Southern Pundits theoretically advocate 72 Thātās or parent scales, but for the purposes of practical music, feel satisfied with 19 parent-scales only, as these do embrace all the known Rāgās of their system also.

The chief merit of the Northern system lies however in the fact that every derived Rāga or Rāginee possesses some distinct feature belonging to the Janaka or parent Rāga and yet differs from it and other derived Rāgās by a feature individually its own. Hence, though the æsthetic appeal of such a family or clan of Rāgās is generally of a set type, yet it requires great artistic skill in bringing out the distinguishing character of two near-most Rāgās.

The clan idea of Rāgās could not however cover all the requirements of the Northern system and hence alternative arrangements began to be proposed from time to time. Thus some scholars advocated the necessity of assuming more than six fundamental or parent scales and some suggested as many as nineteen. At present there is no unanimity about the minimum number of such parent scales necessary to embrace all the Rāgās of the system. The latest and perhaps the ablest advocate in the field was the late Pundit Bhātkhande of Bombay who based the whole system upon ten parent-scales only, but even his plan has many weaknesses and is not able to accommodate all the Rāgās of the system in a satisfactory manner.

Tāla,—The Third Unity of Indian Music.

Tāla or the singing or playing of every piece of music strictly to a chosen measure of time is the third and the last Unity of Indian music.

As is well known, Indian music, which is homophonic and has no harmony, can show its best charms in the region of melody only. Melody however is a regular change of pitch with respect to time and so proceeds by determinate steps. Hence it has to pay special attention to rhythm. Indian music has consequently developed every phase of it with minute precision and employs several time-measures not known to the European.

A time-measure employs a fixed number of Mātrās or time units; a short syllable means one Mātrā and a long one means two.

The Laya or the rhythmic sense means the ability to maintain precisely the uniformity of the span of each Mātrā or time-unit. The Laya therefore is as it were the soul of every time-measure. There are three varieties of Laya – Vilambita, Maddhya and Druta, corresponding to the *slow*, *medium* and *fast* varieties of *tempo* in the Western system. The Maddhya or the medium is twice as fast as the Vilambita or the slow, and the Druta or the fast is twice as fast as the Madhya or the medium.

In the early stages musical time followed the sequence of long and short as that of the poetic metre used for the song. The time-measure therefore used to possess the same number of bars or divisions as those

of the metrical line or foot. A bar or a beat usually signifies the place of stress. But as the rhythm of poetry mainly depends upon the actual movement not of the time but of the words, it is regulated more by the sense and the length of the words than by the regularity of stress. The measurement of time by quantity or by the number of long and short syllables, does not therefore necessarily contribute to the periodicity or regular recurrence of stress which rhythm in music means. The poetic metres therefore were not at all suited to the requirements of musical rhythm, which framed its different time-measures on the principle of regularity of the places of stress and rest and on further symmetry possible under the circumstances.

In poetry, the meaning of words alone matters, while little value is attached to the emotional power of pure tones. Music however attaches more value to the emotional power of the tones than to their literary meaning and this served to make its rhythm still further independent of the poetic metres.

A Tāla-measure consists of several bars and places of rest.

A bar may consist of two or more Mātrās but the chief constituents of a bar are either a group of two or three Mātrās, joined together or repeated once or twice or more times as required to make up the total number of Mātrās assigned to the bar. The bar is indicated by special stress or accent or by the beat of the hand or by a special conventional sound on the drum. Special stress is given on the principal bar and deliberate silence is observed or some other conventional sound is produced on the drum, to mark

an agreed position of rest. The silence indicates a particular phase of each time cycle and thus helps to maintain the sequence of the bars or places of stress in the measure, accurately

In the old days, as many as 35 Tālās or time-measures were current, but at present, only a few of them are needed On account of the variety in the length of the measure, in the order and number of the bars and in the sequence of the time units or Matras assigned to each bar, the performer has to see his way through a number of voluntary handicaps, which apparently put the quality and culture of the performer to a rigid test Indian music does this by laying it down that the artist must never take freedom with the time measure, much less with the Laya Freedom with the Tala-measure may for once be tolerated but freedom with the Laya, never

Thus, within the limits of the Laya and the time-measure, proper attack and release of syllables and words the deliberate suspension or delaying of some notes, the doubling, trebling or quadrupling of time over a desired portion of the melody or the introduction of small artistic rests are some of the more important artifices commonly employed by the artists

In short, the first Unity discloses the method of selecting a scale in an ideal manner and determines the degree of the consonant or dissonant character of a note and fixes its place in the scheme of tonality, the second by giving prominence to a particular note and hence to a particular consonance or dissonance makes

capital of the consonance or dissonance for an emotional appeal, and the third helps to maintain the flow of the emotion and governs its rise and fall Thus the three Unities of Indian music are the complementary steps of a common musical end in view and together make for a larger Unity viz of giving character to music

CHAPTER VII

The Aesthetics Of Indian Music

The larger unity or the one theme of classical Indian music is to give character to music

Character, as we may see, has its roots deeply laid in the tonal relationship of the notes used and in the melodic progression, as extended in the region of rhythm A song or a tune is the outward embodiment of music, but character is its very soul The processes which bring out the full beauty of this soul form the Æsthetics of music

We shall now give the different æsthetic processes employed in Indian music and see what justification they may have from the view-point of modern science

To begin with every classical song has a poetic theme This is usually very simple in nature It may be in praise of God or of a mythological deity or hero, or of a king or patron In some cases it may be from music itself or be one describing nature But more often than not, it may concern itself with lovers with the conventional slip between the cup and the lip In short, the composition is usually of a simple and homely character Nor does music allow much scope for any special poetic merit, as the meaning of the poetic words and phrases is stifled or thrown into the background so completely, even by the one part accompaniment and processes such as those of the Indian system

that the audience has tn he content mostly with the notes of the music and has often to guess the words. This is true not only of Indian music but of the music of the West also. As Megroz puts it 'the words of the majority of songs are sn poor and even silly, that the loss is not necessarily severe'. In any case, the Indian audience does not feel as much concerned with the words of a song as with the music to which the words are set. Even then the nrtist gives some consideration to the poetic theme. So, when the song is actually sung, it is given first to slow or medium time and the whole song—usually composed of two nnd sometimes of more parts—is sung once and occasionally twice or for more times, so that the poetic theme moy without much difficulty be grasped by the audience.

When the song is sung thus, the improvisation or progression begins. The progression of Indian Music is not a work of o rhapsodic improvisation os some—chiefly Western critics—suppose, but it has some well recognised principles to guide it. It is improvisation in the sense that it needs no rigid preparation as that of the Western System, in which there are many parts, which without a common understanding and previous direction may run amok and entirely spoil the music. In India, 'the artist himself is both the director and the performer and hence there is no academicism about him and his songs simply come off.' Thus the improvisation of Indian music allows greater scope for individual freedom than that of Western

Each one of the three unities–referred to in the previous chapter–has its own reactions or demands on the progression of Indian music, and let us view them in the same order as the unities themselves

The first requirement of the first unity is about the correct intonation of all the intervals of the scale of the chosen Raga This is secured by a rigorous observation of the principle of tonality referred to in a previous chapter Incidentally, the drone, being the instrument of reference, must have an unquestioned predominance in the accompaniment Other instruments of accompaniment have a secondary place in Indian music, as these, on account of the instrument player s unavoidable lag behind the singer, are in most cases unable to accompany the music at all Under the circumstances, the most they do is either to play the salient notes of the music or simply strengthen the drone The instruments therefore lose their speciality as accompanying parts and simply converge as it were into the drone

The next step is to make the best attempt to preserve the quality of the notes employed and make the music as much expressive as possible

In the case of vocal music this is done by proper voice training In Indian music due regard is therefore paid to voice training, but it is necessary to remember here that voice—training as understood in India is different from voice-training as understood in the West In Indian music, as each song is cast in one definite mood and employs one scale viz that of the chosen Rāga alone, there are no sudden variations in the

power and quality of the voice On the otherhand it always seeks an opportunity to make a smooth return to the tonic note In the Western system however the music is more of the dance type and on account of the various parts develops a powerful *mass of tone* and effects sudden changes in the mood Again imitation of the cries of birds and beasts of the rustling of the leaves or of the thundering of the clouds, of the surging of the billows or of the roaring of a brook, *counts as musical performance in the West whereas* such performance has no place in Indian music It is no wonder, therefore if the voice production of an Indian performer sounds either hollow or monotonous to a casual listener who is normally trained in a diametrically different tradition To return to our point every Indian performer is expected to do his best in training the voice This is achieved by including in the general training a practical course in Alapa making or *Vocalisation* so necessary for the beginner to attain proficiency in vocalisation and for the advanced student to retain the proficiency once attained

Voice training

The Alapa—*exercises* attach special importance to Resonance and Poise as these are the two essential things that develop the quality of the voice Proper breath control secures poise whereas resonance depends chiefly upon proficiency in immaculate articulation The Indian *musician* does not of course prescribe any particular exercises in breathing but takes care to see that the Alapa exercises are so *graded* as to develop the power of sustaining the voice with the greatest possible ease He therefore makes it a point

to avoid any jerks or shocks in voice production and develops his capacity for sustaining the breath long enough by practicing the vocalisation to slow time. For the purposes of resonance, proficiency in immaculate articulation is attained by a persistent practice in cleanly reproducing the vowel and consonant sounds occurring in the different words. Thus, every syllable is cleanly attacked and after due suspension is released with the utmost possible grace and ease. The few syllables, which satisfy all the expectations of such a practice, are specially singled out from the rest. The Nom-Thom lessons are meant for such a practice only. As these lessons form an integral part of the practical training of every musician, it is necessary to consider here the degree of scientific interest attaching to the same.

Both vowels and consonants are vocal sounds and the musical quality of the voice is largely modified by their presence or otherwise. When breath, which throws the vocal chords into action, passes from the larynx on to the lips, it comes across the various resonating cavities in the mouth and causes the resulting sound to be amplified The amplification is further modified by the position of the tongue and the degree of the opening or closing of the teeth and the lips

These cavities consist of the Pharynx or the upper part of the throat, the soft palate, the hard palate and the Nasal cavity. The teeth and the lips in collaboration with the tongue can be used with advantage to produce a good vocal tone. The strain on the vocal chords can therefore be reduced to a

minimum by the judicious use of these cavities and by the proper control and adjustment of the tongue, the teeth and the lips

Of all sounds, vowels require the minimum of effort for, a vowel is breath unimpeded by any of the organs of articulation but only moulded or modified into different sounds by alterations in the shape of the mouth In phonetics vowels are often classified as *tense medium* or *slack* In music however, there is no need for such a distinction and it is enough to know whether a vowel is long or short a single sound or a diphthong In Indian music long vowels are preferred to short and diphthongs to simple ones

Among the consonants some are voiced and some are unvoiced The voiced consonants are generated by the vibrations of the vocal chords but the unvoiced ones are not so generated The latter are purely mechanical sounds either explosive or frictional in nature Thus the sound of T P etc is unvoiced and explosive in nature That of F S Sh etc is also unvoiced but is frictional in character For every voiced consonant there is a corresponding unvoiced consonant possible In every day speech only a few of the probable number of such sounds are used Music however uses the unvoiced sounds with a distinct advantage and with an equal facility and purpose as the other sounds used in speech

Of the vowels and consonants a vowel sound can be indefinitely sustained without losing its characteristic effect A consonant on the otherhand is not a persistent sound being practically a new way of com

mencing and ending a vowel sound The requirements of a musical note are therefore fully satisfied by a vowel sound only and on this account all vocalisation consists in sustaining the vowels in the words, for a desired period of time The consonants however lend a further charm to the quality of a pure vowel sound, by creating a variety in the attack and release of such sounds In Indian music the effect is particularly happy when a compound consonant fuses into a vowel diphthong which is sustained for some time and then released Thus some syllables such as Om Nom, Thom Hrom Noum Rheem Dre, Dhru, Tom etc are traditionally used in vocalisation, as these offer special facility and variety of pronunciation, and are chiefly the syllables used in the Alapa—exercises The reason why particular consonants are chosen for the purpose of the attack and release of the above syllables will be clear from the following explanation

All consonants except the gutterals are formed in the front part of the mouth An easy control over the movements of the front part of the mouth is therefore an advantage in vocalisation Firstly it gives ease of pronunciation of a majority of the speech sounds and secondly it amplifies the sound without the risk of giving *a shock to the glottis* On this account the Indian musician makes it a point to place the tongue well forward in the mouth In the case of singers in whom these muscles get sufficient training even in the course of everyday speech, reading or recitation, and hence the importance of cultivating the habit of

good speech, reading or recitation, from the very childhood In Indian music, however, this training is not left to chance and a course in Nom-Thom or Alāpa-making is invariably prescribed for every student of music. The peculiarity of such a course is that it employs such syllables only, as would always place the tone well forward in the mouth, and provide sufficient training for the voice The syllables of the Nom-Thom-group are, as will be easily seen, of the required nature, as they are formed only in the front part of the mouth. Between themselves they include all the essential vowels both simple and diphthong and employ such consonants only as place the tone well forward in the mouth

An Alāpa moves both in pitch and time and is thus a simple form of musical progression, in which the two well known principles viz of rhythmic advance and procedure by determinate degrees are honestly followed It is executed first to a slow, then to a medium and finally to a fast measure of time In an Alāpa the dominant notes of a Raga always receive special prominence, thereby making their comparison or contrast with the drone, quite distinct

In the Dhrupada, (see Chapter VIII) the Alāpas are given with the traditional syllables before the song proper commences In the other types, they are given in the song proper and with the syllables of the words of the song itself The Alapas are first very short and always end on the tonic note Each successive Alapa gradually accommodates more and more syllables and hence accommodates fresh notes in addition and

stretches over a greater part of the time measure The final link in the Alāpa ends on the tonic and is followed by a fixed link, called the Jodāchā (joining) Alāpa, which leads from the tonic to the burden of the song and thus completes the individual cycle of Alāpās.

When all the Alāpās are sung, the Tānās or regular melodies begin. The difference between an Alāpa and a Tāna lies in the fact that in the Alāpa the salient notes of the Rāga receive special prominence, both in magnitude and time, whereas the Tāna proceeds by equal steps without preference for any one note. The simple Tānās are sung with a single vowel-sound advancing in pitch by the steps of the desired melody They are followed by what are called Bol-Tanās i e. Tānās in which the advance takes place by the vowel-sounds of the successive syllables of the words of the song itself

The progress of both Alāpās and Tānās takes place by four successive stages In the first stage, the advance is by Ārohi-ascending-steps, in the second, by Āvarohi-descending-steps, in the third by Sthāyee -stationary steps-the same note repeating itself and in the fourth and the last by Samchāri-roaming-steps. From the very ancient days, Indian theorists, without exception, have advocated that a fundamental difference exists between the processes of each of these stages, both in point of the quality or the character and the apparent pitch of the notes

Thus in ascent, as we proceed higher, the notes become more and more vigorous and individual in

character, whereas in descent the case is the reverse Thus the *feeling tone* or the individual æsthetic value of the notes is different in the two processes This also is one of the reasons why the *enharmonic* effect is distinctly visible in Indian music This is especially true of the notes which are distantly related to the primes of the drone—the higher form occurring in the ascent and the lower one occurring in the descent On this account the character of the note, though not much changing, does change slightly in the two processes

In the Sthayee or stationary form of progression, the same note is repeated several times over, but, between two such repetitions the neighbouring note—usually the one just below—throws its shadow This is especially noticeable when the tonic or its Octave is repeated In this case the sharp Seventh, acting as a leading note, as it were, throws its shadow between two such repetitions

In the Samchari e the roaming or complex form of motion, the *enharmonic* changes do take place and can be determined by the same rules only separately applied to each ascending descending or stationary section of the melody In short, it is not sufficient to know the scale of a Raga but it is necessary to know further the different groups of notes functioning in the Raga, with their proper sequence of ascent, descent, stationary or Samchari form of motion

In an Ālāpa, the Meenda or glide is often employed and it may sometimes extend to a full octave or even beyond In the glide, the voice or the note does not

move by steps, but glides on continuously. This may apparently be considered as violating the well respected principle of procedure by determinate degrees or steps The contradiction however is only superficial, for, the motion of a glide has a twofold significance

In the glide, the voice is stressed just when it passes up or down through the pitch of the legitimate notes of the Rāga scale and remains perfectly smooth and gliding for the rest of its journey The points of stress, therefore, mark the beginning of fresh steps and thus form a legitimate piece of melody against the gliding background Thus in a glide, the principle of procedure by determinate degrees is truly observed in spirit In Western music also, the glide is frequently employed, in spite of the fact that the general theory of that system does not tolerate its use Thus in the solo performances, particularly those on the violin, such glides are frequently played and as Prof Blasserna tells us are played with great effect also Then the general abomination of the glide may be due to the fact that in a system which is keen on harmony, a glide may become a source of great hindrance The exact moment of stress seldom happens to be the same with different people, even in the case of a single gliding note and shall therefore be grossly missed in harmony where a number of notes are employed and are played by different people To save music from such a travesty of things the Western system puts a general ban on the glide But as Indian music is homophonic, there is no such risk and hence it uses the glide freely and with distinct effect also In a glide, except

for the moment of stress, there is a general suspension of the notes and this establishes a sense of stretch or tension and creates a longing for an early relief being restored The relief comes when the moment of stress just arrives or the suspended note or voice finally resolves into a well-defined consonant note of the Rāga scale, usually the tonic The glide therefore plays a great æsthetic role in Indian music and is a very favourite ornament with all performers

As will be seen from the explanation of the nature of a glide, a note becomes legitimate if it receives special stress and duration or else it is merely a passing note and does not gather enough moment to make an impression at all A note can therefore be pushed into the back ground or avoided in two ways, either by omitting it altogether or by using it merely as a passing note, without any stress or duration This is what the ancient theorists of Indian music meant by Varjyatva or omission of a note It is either by Alpatva i e by lightly passing over it or by Anabhyasa or Langhana, meaning total omission

Thus, as remarked elsewhere, every Raga is a special æsthetic scheme, having an individuality even in its physical form So in the case of Ragas which are very close to one another, utmost care has to be taken to preserve their individual character in tact This is done by supplementing the Vadi Samvadi arrangement and the melodic specialities or rules of each by the proper choice of the Alapās and Tanas of their ascending or descending motion, and of the use of glides or otherwise

We now come to the all important and ever interesting aspect of Indian Music viz. its capacity to make an emotional appeal. The Rāgās and their Rasās — emotional appeal — have been a subject of very close attention even from the very early days and ever since have given rise to fantastic notions and surmises about them. Thus, there have been a few who think that music is merely a passing show or a pastime and has nothing to do with the inner mechanism of emotion. There have been others who declare that music can give rise to any and every emotion and can develop it to any degree of intensity. There have been yet others, who would assign this or that emotion to a Rāga, according as it would please them. There is thus a mess of all things, with the result that there have been keen differences of opinion on the point.

The problem of the Rāgās and their Rasās or emotions is not however as elusive as it is thought to be, and if attempted with the proper spirit of critical analysis, admits of a fairly rational solution. To begin with, the problem has a threefold aspect. Just as the seer of an object, the object, and the process of seeing are the complements of a single action, the musician (or the listener), the music and the process of performing (or listening) are the complements of one and the same action, resulting in a certain musical appeal.

Hence, the nature and the degree of the emotional appeal may have much to do with the peculiarities of each of these. The performer and the listener have a certain initial freedom of naming or choosing their

own material viz the Rāga and the song etc, but having chosen the material once, they have to accept the law and order of the chosen theme as also its limitations In music, sound being the medium, both the performer and the listener need have a clear understanding of its laws and must, from the first, pay due regard to them The skill of the performer then lies in interpreting these laws in as many beautiful ways as possible and in creating different beautiful orders and patterns, out of them Though music thus offers great scope for personal skill and variety, yet under the veil of this variety, there is always that gracious presence of a unity, the unity based upon the observance of the physical laws In considering the problem of Rasās therefore, precedence ought to be given to the laws of harmony over the likes and dislikes of individuals These laws will ever remain what they are and will not alter like the tastes of individuals Hence the problem of the relation between the Rāgās and their emotional appeal must be considered independently of the likes and dislikes of men Further, it must in no way be considered from the viewpoint of the other arts-particularly of poetry Its consideration has however been vitiated by such wrong notions and the vitiation is almost complete! Personal likes and dislikes tacked on unintelligible ancient practices, rivalry for doing the gigantic or humanly impossible feats, want of a general education or scientific grounding and a general conservatism among the artists are mainly responsible for this sorry state of things! Those, who maintain that the problem of the emotional appeal of the Rāgās admits of no solution, either suffer from the

above defects, or want to take undue liberty with the laws of harmony. From a purely rational point of view however, the laws of harmony ought to primarily figure in the solution of the problem. Then it may be for the artist to give within the limited freedom allowed- such a setting to the Laws as may best serve his motives. True art therefore lies in the intelligent interpretation of these laws rather than in taking undue freedom with them, as also in not allowing the other arts to react on them in an unhealthy manner. Thus in analysing the problem of the Rasās, we must look for the seat of the emotional appeal in the laws themselves.

Consonance is the first and foremost consideration upon which the laws of harmony are based. Music therefore employs consonances for a pleasant and hence for a bright effect.

Dissonance, on the other hand, is jarring and deals a shock which the ear protests So music employs dissonances for an unpleasant and hence for a dull or sad effect.

For the purposes of Indian music, the degree of consonance or dissnonace generated by a note is easily determined by simply knowing how the note is related to the Tonic-harmony of the drone. As already investigated in a previous chapter, the resultant notes of this harmony are the first few harmonic upper partials of the fundamental note—which is the most powerful of all. Hence the comparison of a note with the tonic harmony of the *drone* is primarily a comparison with the fundamental note itself.

Then to determine the character of a note, the following two rules will suffice

1 The physical appeal of a note is pleasant (bright) or unpleasant (dull) according as a note is a consonance or a dissonance

2 The closer the harmonic relationship of the note with the tonic the greater is the degree of consonance and the further the harmonic relationship the greater is the degree of dissonance, generated by the notes

The following table gives the individual character of each note in relation to the tonic note, as per the two rules given above —

1	Absolute consonances –	Unison and Octave
2	Perfect consonances –	Fifth and Fourth
3	Medial consonances –	Major and Minor Thirds
4	Imperfect dissonances –	Major Second and Sixth
5	Perfect dissonances –	Minor Second Minor Sixth Major Seventh Augmented Fourth

In Indian music the Minor Seventh is usually associated with the Fifth (or the Fourth) and then it is a medial consonance In other cases, it belongs to the class of imperfect dissonances

These two rule then determine the individual character of each note But as a Rāga does not employ only one note but necessarily employs a group of at

least five to seven notes, what would be the Rasa or the feeling tone of the Rāga may seem to remain yet undecided. But it should be remembered here, that the Rāga-system is based on the idea that each Rāga is to give prominence to one particular note in preference to others and so should become the vehicle of what that note stands for. Thus in a Rāga, the part played by the Vādi, being the most emphatic, survives to the end and maintains its swing and potency all along, by pushing the clashing detail out of sight, by less emphasis, attention or prominence. In choosing a Rāga, therefore, its musical theme or better its emotional appeal is chosen as well, and the latter is mainly governed by the character of its Vādi or dominant note. The Vādi note therefore serves as an index, as it were, of the kind of appeal a Rāga may put forth.

As there are three types of notes, such as, absolute or perfect consonances, medial consonances and dissonances, the corresponding musical appeal of the respective Vādi notes will also be of three different types.

The appeal would put on an openly gay and bright character for consonances, whereas for dissonances, it would be openly sad and dull or depressing. If the Vādi happens to be a medial consonance, the appeal would neither be very bright nor very dull, but would be intermediate between the two and thus would seem rather indefinite in character. Under the circumstances, the uncertainty, in the part played by the medial consonance of the Vādi note, is removed by

further stressing either the consonant or dissonant notes from the remaining part of the Raga-scale

The consonances can be stressed in two ways, viz by giving them individual prominence or by passing over the dissonant notes lightly or by omitting the latter altogether The same is true of the dissonances also

In this way, if the Vādi is meant to have a bright appeal, the consonances ought to predominate and if it is to have a sad or depressing appeal the dissonances must receive greater prominence The appeal would then be fairly definite in character It would of course be not very powerful but would on that account be subtle and hence would require great skill and insight in its proper delineation

In this manner, we can make music as much bright or dull, gay or depressing as we like, by choosing the Vadi note in a suitable manner and accordingly impress the ear physically But such music may not necessarily touch the mind nor move the heart To do so, the mind has to be led from the purely physical into the æsthetic or emotional regions To stir the mind, a centre of interest must be created and the interest must be further advanced by raising an expectation which when fulfilled offers great relief and makes for joy and pleasure On the other hand the nonfulfilment of an expectation makes one uneasy and sad or miserable

Interest may be created and further advanced by —

1 The poetic theme

2. Certain actions and expressions, as in a dance, or by
3. The power of tones alone.

Drama employs all these three together and is thus a mixed form of art. But in its purest form, each art employs its own medium and does its best in that medium irrespectively of the others. So, poetry employs only words, painting depicts certain postures or scenes, dancing employs only bodily actions and expressions. Similarly, music employs only the tones and through them develops the power to make an emotional appeal. In the fitness of things, therefore, the poetic and other bearings, although modifying the musical effect to a certain extent, have a secondary place in the consideration of the æsthetics of music as a pure art. The æsthetics of music must therefore concern itself with the intelligent use of different musical sounds on their acoustic merit only. This merit, or the artistic potentiality of a musical note, depends upon the following :—

1. The harmonic relationship of the note towards the tonic or fundamental note, as also towards the other notes of the scale.
2. Individual tonal variations.
3. Individual rhythmic variations.

Thus under the first category, a comparison with the fundamental discloses the individual character of a note, either as a consonance or dissonance and as previously explained, puts on a pleasant or unpleasant appeal. Next, the consonance of a note becomes more

bright by associating the note with another which is less consonant than itself If the note however is associated with another more consonant than itself then the degree of consonance is toned down

Similarly, a dissonant note, when associated with another still more dissonant, appears less dissonant and when associated with a note which is less dissonant or comparatively more consonant than itself, appears more dissonant by the contrast provided

To make the contrast hold enough so as to easily attract the attention of a listener, the note, which is intended to receive greater attention, is distinctly hinted at, but is deliberately delayed by the intervention of a second note, which is sustained a little *too* long This delay, at a *critical* moment when a note of some prominence is clearly hinted at but is purposely avoided, establishes a sense of tension, to which the mind reacts by insisting upon its speedy removal and thereby shows a yet greater preference for the delayed note This is a very favourite artifice of the Indian singer and corresponds to the *appoggiatura* of the European system In Indian Music if the Raga is intended to have a bright appeal the tension is removed by making a graceful return to the dominant note of the Raga or more generally to the prime notes of the drone, which being the most consonant enliven the bright and gay character of the music If however the Rāga is meant to make a sad or a pathetic appeal, the tension on account of the delaying note is allowed to remain for a much longer time or as in some cases, is not at all removed, nor does the delaying note

necessarily lead to a consonance. The uneasiness therefore persists and is further aggravated, thereby making its effect more touching or pathetic.

In short, the notes of the Rāga-scale may be associated together with a double end in view. It may be either for toning up or down the individual character of one of them or may be for the purposes of *'appoggiatura'*. In the latter case, if the delaying notes finally lead to strong consonances, the effect is peculiarly pleasant. Such consonances are none other than the fundamental note and its Fourth or Fifth, which function as the prime notes of the drone. The Indian Musician therefore uses the notes just preceding or following the primes, for the purpose of leading the music to them. The leading notes are as a rule a semitone below or above the primes. Thus, there are six leading notes in Indian music, two for each prime note. Accordingly, the sharp Seventh and the flat Second act as the upward and downward leading notes for the tonic, the sharp Fourth and the flat Sixth for the major Fifth, and the major Third and the sharp Fourth for the major Fourth. European music uses generally one leading note—the sharp Seventh—for leading to the next higher note, the Octave. Indian music, on the otherhand, uses both the upward and downward leading notes with equal facility and uses not only one or two, but all of them, as required.

The individual character of a note may be further modified by effecting suitable changes in its tonal quality and by subjecting it to rhythmic variations. With the help of such changes it is possible to create

several forms of musical expression which may accentuate the appeal of the Raga By virtue of the tonal quality and rhythmic advance different types of musical expression have much in common with certain every day associations and experiences and on that account, lead the mind easily into the sphere of parallel activity and experiences from life Such musical expressions therefore make the character and extent of the musical appeal more specific Thus, bright and cheerful sounds remind us of joyful things, harsh and loud sounds of anger or power sad and subdued tones of sorrow bereavement or fear and so on The above experiences are intimately linked up with changes in the quality of the tone There are other experiences which are linked up in a similar manner with changes in their rhythmic bearings Thus steady and sustained notes remind one of steady and peaceful things and a rapidly varying voice of impatience or hasty action A strained voice signifies effort a checked voice reticence or shyness and a well regulated speech shows clarity of thought and definiteness of purpose Thus by a judicious choice of the tonal and rhythmic forms of expression the mood of a Rāga can be firmly established and music may truly become a vehicle of an emotional appeal of various degrees of intensity

In Indian music such changes are technically known as Gamakas of which there are a few standard or stock forms which form a necessary part of the education of every student of the art

So far we have briefly considered the different æsthetic principles and artistic devices that are

usually employed in Indian music to make it fully expressive. Emotion in music must not however be missed for emotionalism. Emotion, if it is to be represented sincerely, must be understood thoroughly, hence it must be always under the control of the singer's mind. In its naked form, an emotion may sometimes gather so much force that it may become the cause of acute physical pain or undesirable organic sensations Under the circumstances, the emotion becomes unbearable and hence unenjoyable Music does not aim at representing the emotions in their naked form If music were a blind imitation of life or were meant for awakening the animal instincts in man, it could have hardly provided the kind of gentle enjoyment it provides now, nor could it have made life any the better or nobler for that In expressing any emotion, music tries to dominate its brute force through artistic expression As an illustration, it should be noted that Folk music and dances do put up a very powerful emotional appeal but fail to make any musical effect, worth the name The emotional power is due to the crude and blind imitation of life in all its acuteness, which however, for want of domination through musical expression, apparently becomes uninteresting and often painful It is on this account that barbaric or crude forms of music fail to provide any enjoyment 'in which there can be ecstasy without grimace or submission without tears

Refined music, therefore, does not stop with the mere generation of an emotion, but by uniting it with musical form, conquers its brute force, thus trans-

forming it from a material into an ideal form The Rasa or the emotional effect of a Rāga belongs to such a class of emotions In the beginning, it seems to merge into common emotions but really turns out to be such as finds no existence in nature This is why the Rasa problem of the Ragas has become so naughty For, to those who wish that the emotion must appear in all its acuteness, the Rāga music would be gentle beyond toleration To those who revel in gigantic feats and musical acrobatics, music may have no value as an art, but is a matter of mere pastime or sport There are others who no doubt consider music as a great and noble art, but who see no reason why the mood, instead of remaining the same throughout, should not change at will, as in the music of the West The mood of Western songs does change according to the impulse of the moment, but at the same time, it should be remembered that such changes are worked up by transposition at will, by the introduction of specially prepared discords not belonging to the scale proper and by other artistic means which the unities of Indian music cannot tolerate even for one moment On the otherhand, Indian music does not allow transposition, insists upon using one and the same scale throughout, and of that scale also, a chosen note or a particular consonance or dissonance is to predominate in preference to any other notes Under these circumstances, it is no wonder if the mood remains only of one kind So long as the Unities of Hindusthāni music remain what they are the result cannot be otherwise The inability to change the mood at will is however more than counterbalanced by the several

CHAPTER VIII

FORMS OF MUSICAL COMPOSITION

Indian music has from time to time evolved a number of forms for the expression of its manifold beauties Beginning with the Sāman Chant which had four distinct stages in its progression, forms such as the Vritta, Chhanda, Geeta, and the Prabandha, became current in the years that followed Each of these again consisted of four parts such as the Udgrāha Melapaka, Dhruwā and the Abhoga The Prabandha form seems to have been current up to the late eleventh century, for, it is to this period of time that the famous Geeta Govind of Jayadeva, composed in the Prabandha form, belongs These Prabandhās of Jayadeva have however only two parts—the Dhruwā and the Abhoga—instead of all the four It thus appears that the Prabandha form also was in a stage of evolution and was replaced in course of time by other forms, such as the Kritics and the Bhajans etc There is ground to believe that along with these classical forms of musical composition, there were simultaneously current some other forms also, which were rather free or loose in character and were perhaps the cause of much chaos in the few centuries that followed Jayadeva The first to stop the rot was Raja Mana (1486–1526 A D) who either invented or patronised the famous Dhrupada style This style, so well known and respected even up to this day, was further perfected by great musicians like Haridas

Swāmi and his famous disciple–Tānsen, in particular and found great favour with Akabar's Court.

The Dhrupada–as its meaning indicates–is the strict style. A style to deserve the name strict must of course contain the essentials of a system in a clear and simple form, and it is so with the Dhrupada-style. It is laid down that in the Dhrupada, there must be no flourishes or embellishments in its progression, and that it should proceed by determinate steps only. In other words the Dhrupada strictly follows the two well-known principles viz. of rhythmic movement and procedure by determinate degrees. As already remarked in the preceding chapter, these principles actively figure in the Alāpa-exercises, which the Dhrupada-singer in consequence must have thought as a fit prelude to the Cheeja or song proper. These Alāpās do not as a rule employ any fixed time-measure but only observe the broad principle of rhythmic-advance, and are intended to elaborate the beauties of the chosen Rāga, in all its details. This practice of giving the Alāpās as a prelude to the song proper perhaps corresponds to the Udgrāha and Melāpaka stages, not met with or mentioned in the Prabandhas of the Geeta Govind. Perhaps, they were then too well-known to need any mention!

To return to our point, the Dhrupada-singer first does his best in elaborating the chosen Rāga with Alāpās, sung or played in the order described in the preceding chapter. Next he begins to give his Cheeja or song proper, at first to slow time. The poetic composition is so composed and set if necessary as to

correctly observe the sequence of the long and short required by the chosen time-measure This sequence does not admit of any variations on any account and at any stage of development The poetic words of the composition are, as it were, screwed to a rigid framework in the form of the time measure So, the song, though remaining academically pure, soon becomes uninteresting The only opportunity for some relief is provided when a well-timed return to the old time-measure is made after doubling trebling or sometimes quadrupling the time or tempo of the song Such changes in the tempo result in a variety of cross metre and require great precision and personal skill

The Dhrupada-style requires a manly and powerful voice, which must be further capable of sustaining its quality, in spite of the variations of time or tempo, mentioned above

In the old days, a Dhrupada used to have four poetic divisions or parts, but at present it usually possesses only two and more in exceptional cases only These parts in their order are known as the Sthāyee, Antarā, Samchāree and Abhoga

In the Sthāyee, base notes are employed on a very large scale and the musical sentences and phrases first circle round the Vādi or the dominant note of the Rāga and then return to the tonic or the fundamental

In the second part or the Antarā, the notes from the middle octave and particularly those from its

second tetrachord are given free play, and the musical phrases first lead to the higher Octave and then make a return to the fundamental

In the Samchāree or the third part, the music usually starts with the base note of the second tetrachord, then leads to the upper Octave, not with a straight and simple form of melody, but with artistic twists and curves and the melody thus oscillates, backwards and forwards, as it were In this part also, the notes do not go beyond the Octave and usually end on the tonic or the other prime note of the drone

In the Abhoga or the fourth part of the Dhrupada, the performer employs notes from all the three registers and tries his best to go to the highest possible pitch which he can reach with ease and effect

At present, Dhrupadās consist of only two parts and it is in the second part or the Antarā that the performer does his best and compresses everything that otherwise used to belong to the remaining two parts

As already remarked elsewhere, the poetic theme of a Dhrupada is usually very simple and is musical first and poetic afterwards

The chief merit of the Dhrupada-style is in its strict adherence to the two fundamental principles viz. of rhythmic advance and procedure by determinate degrees The constant aim of the artist is therefore to make the highest possible effect with a few simple clean notes, unaccompanied by any flourishes, shakes or such other touches of grace The Dhrupada there-

fore easily preserves the purity of the Rāga. It is thus a clean and correct form of music and rightly deserves the name "strict style" conferred on it, and is on that account held in very high regard by successive generations of musicians

The chief defects of the Dhrupada style are however its monotony and absolute denial of any scope for musical grace or delicacy. As no flourishes or embellishments, by way of Tānās or such other touches of grace are allowed, the Dhrupada soon becomes a self recurring musical feat Again, the variations of tempo give the upper hand to rhythm over the tonal shades, which though manly and powerful soon become monotonous and wear out the patience of the listener in a short time

Hori, sung in the Dhamār time measure and on that account known as Dhamār itself, is another form of musical composition, which is similar to the Dhrupada in its structure and progression The poetic theme of the Hori, usually concerns itself with the playful incidents of the childhood of Lord Shree Krishna

Another form of musical composition is the Tarānā, which employs only the Alāp syllables, viz Nom, Thom, etc The Tarāna employs tones for their tonal values and altogether ignores the literary or the poetic merit of words and so in one sense is an ideal form of purely musical expression In the Dhrupada, the Alāpās which form the prelude are given to a very slow time and employ no fixed time measure as such The Tarānā is a refined type of such Alāpās, as it were, for it is sung to a fixed measure of time and is

further developed as an independent Cheeja or song, of which the tones and not the words speak As the Tarāna is a composition in a strict measure of time and must put up an appeal without the aid af poetry, it requires great personal skill and ability of intell igent interpretation, on the part of the artist Since it is sung usually to a fast time measure and employs numerous types of rhythmic arrangements, it helps the artist to develop a subtle yet an accurate sense of rhythm and a facility of musical improvisation at a very short notice Thus in the Tarānā, the slow Alāpās of the Dhrupada are linked up into different groups of melodic orders, which serve as model links for the Tana and particularly for the Bolatāna, in which the melody fully brings out the vowel and consonant values of the syllables employed The Tana or the melody consisting of such model links naturally preserves all the niceties of the Rāga Other Tānās, based upon mere permutations and combinations of the notes of the Rāga-scale, do not possess the same merit as those described above On this account, a few good Tarānas illustrating each Raga are always in stock of every classical singer The Tarana thus serves as a training ground in acquiring facility in Tānas and particularly in Bolatanas, stretching over a fixed interval of time and on account of its ability to bring out the vowel and consonant effect fully, can give a good finish to the voice training method previously described

Thumri is another interesting form of musical composition A majority of such songs employ scales which are usually met with in the Folk songs and

Their music though not much differing from that of the Thumri is not however of the same high order.

The Thumri proper is sung to a slow time and it is only for removing the monotony of rhythm, that the time is temporarily doubled or a Tāna is taken as a finishing stroke and then a return is made to the slow time.

The whole technique of Thumri-singing lies in passing from one note to another in a very graceful manner and particularly in introducing the Octave and the Fifth, which are deliberately delayed by the intervention of a less consonant note, used as a leading note.

The glide also is a very favourite ornament of the Thumri-singer and is specially helpful in introducing notes which need special treatment Thus in a glide, the more important notes of the Rāga are stressed and the less important are lightly passed over. As described in a previous chapter, the glide, by suspending some of the notes is helpful in establishing a sense of tension which is removed only when it returns to the dominant note of the Rāga or to the fundamental or the other prime note and is on that account freely used to heighten the effect of the Thumri. The Thumri-form is essentially emotional in character, in spite of the fact that the scales used are plain and simple in form. What then makes the appeal so emotional ? It is nothing but an ability to make the most of the æsthetic value of each note by a process either of associating, contrasting or suspending such notes in the light of the

poetic theme In a Thumri most of the æsthetic processes which have a root in the tonal touches are therefore actively present The Thumri therefore though simple in form and scale requires a great mastery of these delicate processes and hence is the meeting ground of the best in the Folk as well as the Classical type of Indian music It is no wonder therefore that within its very limited field of Ragās the Thumri is equally popular both among the masses and the more advanced classes

The next form of musical composition is the Tappa It employs the same Ragās as those of the Thumri form Its field is therefore very limited The Tappā does not aim at a slow or gradual progression of the theme which is usually in the Punjabi or Pushtu language Even from the beginning it revels in ornamental flourishes at the occurrence of almost every accented portion of the bar—usually signified by a long vowel—and builds up the melody by elaborate turns and trills rather than by a glide which is scarcely used in a Tappā The turns and trills are known as 'Murkies of which there are several subvarieties such as Khatka Gitkad Jamjama Sansa Ansa &c. These Murkies are a speciality of the Tappā and provide good practice in developing vocal facility in singing several kinds of delicate Tānās The one point to be remembered about the Tānās or melodic flourishes of the Tappā is that whether the Tāna is simple or ornamental the successive links, taken up or down are taken step by step only and without any break between them A melodic or orna-

mental phrase begins on a bar and continues over its full extent. Then another phrase begins on the next bar and continues over that bar and in this manner the melody moves over all the four bars or stages or spans of each cycle of the Tappā-measure. Tappā literally means a stage or a halting place on a journey and since there are four such stages in the Tappā measure, the style is named as Tappā itself.

We now come to the most important form of musical composition viz. the Khyāl, which, for the last two hundred years and over, has almost monopolised the attention of the best musical brains. The Khyāl is composed in a number of time-measures such as the Tilwadā, Zumrā, Dheemā Tritāl, Adā Chautāl, Ektāl, Tritāl, Zaptāl, &c. The Khyāl has two varieties viz. the Vilambita or the great Khyāls and the Eken or the short ones. Whatever the variety, a song in either has two divisions viz. the Sthāyee and the Antarā.

The great Khyāls, of course, employ the longer time-measures and are sung to slow time. These were first derived from the Dhrupadās and have therefore to be developed in the beginning much along the same lines. The slow, steady and sure development of such Khyāls enables the music to preserve its serenity and weight as in the Dhrupada-style. After singing the Sthāyee once or twice completely, the Antarā is sung once, so as to enable the listener to grasp the poetic theme without much trouble. Then a return is made to the Sthāyee. At the end of the first phrase which usually leads to the Sam or the

chief bar of the Sthāyee, Alāpās are gradually appended The Alāpās at first extend over two or three notes only and so are very short They usually extend to the Vādi or the dominant note of the Raga, failing which to the subdominant or the Samvadi note The second Alāpa is given by adding one more note to the first, the note to be added being the next higher or lower note according as the Alāpa first ascends or descends Three such Alāpās are given and are followed by the first phrase, which closes the cycle on the chief bar of the measure Then the Alāpās grow gradually longer and extend beyond one cycle of the time-measure and a corresponding change in the point of their start is previously contemplated over, so as to end them in time and return the music invariably to the chief bar without fail In such Alāpās the glide is frequently employed with great effect Having exhausted the simple types of both the ascending and descending Alāpās in this manner, a start is made with the Vakra or more elaborate Alāpās Having done with them also, the Alāpās are given to faster—usually—duple time, so that they generate simple Tānās out of them When the principal types of such Tanas are sung, the Sthayee is sung once again, thus indicating the end of the first stage in the progression

Then the Antara is sung and a process similar to that of the Alapas in the Sthāyee is followed, with the only difference that such Alāpās begin on the base note of the second tetrachord or if the dominant is very close to it, on the dominant and end on the upper Octave instead of on the tonic note This may

bring to the notice of the reader that there is a close similarity in the Antarā of the Khyāl and that of the Nom, Thom, Alāpās in the prelude to the *Dhrupada*. After elaborating the Alāpās in all their details, a second return is made to the Sthāyee or the first part of the song. This time the Alāpās are elaborated not by lengthening a single vowel sound, but are given with constantly changing vowel sounds, which are further enriched by their association with the consonants occurring in the words. Such Alāpās are called 'Bol-Alāpās.' By and by, at the end of each Bol-Alāpa, small Tānās are appended and these become gradually longer and more frequent. The Tānās replace the Alāpās completely, just when the latter are almost exhausted.

The third stage now begins, when a full and free scope is given to all kinds of Tānās which of course obey the same order of precedence as the Alāpās, both in the tempo and direction of motion. In the Tānās, there is always a point-to-point race between each new step in the melody and each Mātrā or time-span allowed to the note or such a group of them and the excellence of the performance lies in the perfect agreement between the two. Such an agreement alone holds the balance of the song. To relieve the monotony of the Tānās, the performer occasionally sustains the most consonant notes such as the Octave and the major Fifth and stays on them long enough —say for half or the whole of one cycle of the time-measure. In reaching such notes, the major Seventh and the sharp Fourth are used as leading notes, which *brighten the music still further*. *Another way of*

enlivening the effect of the Tānās is to intersperse them with Gamakas and particularly with glides which often stretch over an octave and more These relieve the listener, for a time, from the rapidly advancing rhythm The strong assertion and sustaining of the fundamental note and its Octave or the Fifth serve another musical purpose, in that they help the performer to maintain in tact his sense of correct intonation and allow him some time to think over fresh methods of improvisation

In the fourth or the final stage, all kinds of Tānās, both of the simple and Boltāna-type are executed in all their complex forms In such Tānās there is usually a fusion of the two types They generally employ quadruple time and embrace as much of the three registers as may be possible for the performer, who is expected to do his best, both in point of the elegance of the performance and the rapidity of time-keeping

To the second variety belong the Dheri or short Khyāls, which are usually in medium Tina Tala and are first sung to medium and then to fast time. These Khyāls have comparatively lighter themes such as those of the Thumries Usually they are so composed as to accommodate one syllable in one Mātra or unit of time, or sometimes more syllables also There is therefore hardly any scope in such Khyāls for slow Alāpās or Tanas and much less scope for a glide Such short Khyāls are not therefore ideally complete units in themselves, in as much as they are capable of only such development as belongs to the third and fourth stages of the

bigger Khyāls. The practice therefore is such, that a bigger Khyāl is fully developed over the first two stages and is followed by a short one, which develops the third and the fourth stages further. The third stage requires faster time and then it becomes a little awkward and inconvenient to give a bigger Khyāl with a grave theme originally meant for a long and slow measure of time. The bigger Khyāl is then purposely brought to an end and the remaining part of the progression is given with the new or the shorter Khyāl, which is then taken up as a continuation of the bigger one itself. It is for this reason that the Khyāl style uses a Jodi or pair of songs to bring out the full beauty of a Rāga. It first uses a bigger Khyāl for the more serious and steady part of the development of the Rāga and then a short one for depicting the lighter and more rapid portion of the same.

From the above remarks, it will be seen that there is a great similarity in the development of a Khyāl and a Dhrupada at least in their first half. As the Khyāl employs the glide and the other technique of the Thumri, it incorporates in itself some features of the Thumri also. In the Khyāl, the Boltānās and Tānās employing Gamakās remind one of the Tarānās also. Again as the Khyāl offers a free scope for executing Tānās both short and long, simple and complex, with trills and shakes and such other forms of grace, it has much that belongs to the technique of the Tappā.

In short the Khyāl-style incorporates in itself the very best of each form of composition and on that

account easily surpasses the other forms. This is the secret then, why the Khyāl of all forms has been receiving the homage of all music lovers for the last two centuries and over.

The forms of musical composition previously described may not have been really new forms altogether. They are really reminiscent of the five forms which were current in the days of Shārangdev (early 13th century). Those forms were known by the names, Shuddhā, Bhinnā, Goudi, Vesarā and Sādhāraṇi respectively. Shuddhā means, the plain or pure, Bhinnā means the broken meaning of clear cut notes or steps, Goudi means the sweet, Vesarā means the rapid and Sādhāraṇi means the golden mean or the form which embodies the essential features of each of the previous forms. From the detailed description as given by Shārangdeva, the Dhrupada and the Dhamār compare well with the first two, the Thumri with the Goudi, the Tappā with the Vesarā and the Khyāl with the Sādhāraṇi form of musical composition. Thus the Khyāl may be said to be the Sādhāraṇi or the golden mean of all the present forms of musical composition.

Besides these, there are several other minor forms which however are not academic in character and are often very loose in structure. Their progression has not therefore the same broad basis as that of the classical forms and their merit lies chiefly in the poetic rather than in the musical expression of the theme and in the rapidity and grace of their rhythm.

CHAPTER IX

Some side-issues and Retrospect.

Music and Poetry :—Music and poetry are two independent but very closely allied arts. For the purposes of an artistic effect, each may be employed either in its pure form or in combination with the other. But as a rule, every art has certain charms patent to itself and has also a medium of its own, in which it can show them better than in any other. When however one art works in combination with another, the appeal seldom remains pure and frequently changes the medium of expression also. There is no doubt that in certain cases the appeal becomes powerful and rich by such a combination, but on the whole, it is found that each art is unduly hampered by the other and finds little scope to show its beauties at their best. In the few cases in which the appeal becomes rich, one art really borrows from the other what does not normally belong to itself. When however it is expressly desired to explore the possibilities of a specific art and find out its limitations also, it is necessary to restrict the study of the art to its pure form only. In fact, it is this view which has been adopted as the basis of all consideration in the present work. We however often come across people who have very vague ideas about the function of music and who conveniently ignore this aspect of its study. The cause

of all trouble is in the fact that there are many things common to both music and poetry and these often obliterate the line of demarcation between the two Thus when the art of writing was not known to mankind, poetry used to be recited and as a matter of necessity had to use the medium of sound only But as music also employs the same medium it was thought—as even now some think—that the nature of each art was the same But really this is not so, since poetry uses words for their sense, while music uses them for their sound In the infancy of every language, there may have been some little agreement between the sound and the sense of words, but as we can now see, this agreement must have been of a very elementary character At present, however, with the knowledge of the art of writing, words have as much to do with sight as with sound and poetry may be appreciated to the same extent either by reciting it aloud or by reading it in a silent manner The meaning of a word is the result of an arbitrary choice and hence of convention and is not in the least dependent on the laws of either sound or light Such meaning does not fundamentally differ if the word is either read or spoken aloud or is spoken by different persons of different ages etc Similarly a clear or sore throat makes no difference in its meaning which again remains the same even if read under lights of different hues Hence the power behind a word has its root in a mental faculty which has nothing to do with the medium of sound or light Music, on the other hand, entirely depends upon the medium of sound and the power behind a musical note or phrase has its

origin in the qualities and processes of musical sound itself. Hence it is clear that in their pure form music and poetry are altogether different forms of art. But with many people, it is the fashion to look down upon music as the handmaid of poetry or to suppose that "in the wedding of the arts poetry is the man and music the woman". In fact poetry can as well be made the handmaid of music and follow its dictates. In classical Indian music at least, it is so. As a Rāga is cast in one mood throughout, only such songs of which the poetic theme agrees with the mood of the Rāga are eligible for being sung in that Rāga. Songs of which the poetic theme is unsuitable for the mood of the Rāga are not at all eligible, even though they might be the best examples of the poetic art. Here then, music dictates the mood to poetry and if poetry does not obey, music disregards the meaning of the words altogether and develops the mood, purely with its own material and processes.

The appeal of music is however primarily based on the physical effect of consonance and dissonance and is therefore broadly pleasant or unpleasant in character. Music therefore supplies the mood but not the cause or the exact feeling at its bottom. Therefore, it may appeal to such emotions only of which the nature is openly bright or sad. Hence consonances may rouse in a broad manner a feeling such as of joy, pleasure, hilarity etc. In the same manner, a feeling of pain, pathos, destitution or submission etc., may be awakened, through dissonances. Poetry, on the otherhand, not only supplies the mood but the exact

Jullhā type. In such music the change of the Rāga is necessitated by the impulse of the poetic theme. In light music, therefore, music truly acts as the hand-maid of poetry and offers a *via media* between the Folk and Classical types. Light music is indeed the starting point of stage music or the Opera. Another variety of such music coming into vogue is Film music. The music for the film must be woven out of the emotion and the psychology of the moment and must be part and parcel of the scene or image which is being presented. It must therefore be a thorough representation of the spirit of the picture both in point of its tones and rhythm As these forms of light music constantly undergo a change of mood and technique, classical music, (of which the strong point is to pursue one set mood to a steady and harmonious accompaniment as that of a drone,) is not of any use to them Here our composers shall have to study the technique not only of Indian but of Western music also.

Concerted music or Orchestra:—At present there is a tendency among Indian artists towards orchestral music and this also may need the study of Western music, for its growth and guidance. In the absence of such a study, the so-called Indian Orchestras of to-day merely multiply one-part music on a huge scale and so fall flat upon the ears of the listeners. There are however many Indian Rāgās which may admit of the harmonic treatment, so essential for concerted music. But instead of exploring the potentialities of the Indian Rāgās in

however be plainly stated here, that Indian music being of the solo-type is absolutely plain and simple in its form and does not need a very elaborate type of notation to express its outline. As for expressing its details however, no amount of skill and insight can design a notation which may serve as a true vehicle even of a small fraction of all that the artist means. Indian music is fundamentally vocal and much of it is the result of individual improvisation. As is well known the capacity of the voice for inflexion and subtle variation in tone far surpasses that of any instrument and hence the real charms of Indian music are to be met with in vocal music only. They are on this account too subtle to he correctly reproduced hy the instruments, or accurately and fully recorded into notation.

Under the circumstances, it has been the experience of many thinking people, that any form of notation is as good or bad as any other and that a pupil can pick up the several forms with the same ease, provided he understands the signs and symbols used in a thoroughly intelligent manner. Again the teacher must not stick to any one form of notation and must never make more of notation than of the spirit for which it stands. Otherwise, the pupils–especially young boys and girls–develop preference for one form of notation only—usually the very first taught to them–and develop a mechanical ability of giving long chains of notation, without a grain of any musical quality or sense. Here the old custom of teaching music first by the ear-method is of special

the tonic may be chosen, or another of which most notes are consonant and a few dissonant or vice-versa, or a third with all dissonant notes The broad principle of tonality is not in the least violated so long as the music honestly observes the given set of relationship of notes Thus some sets may be perfectly consonant, some more or less consonant and others perfectly dissonant Western music uses only the consonant sets Indian music uses all the three types of sets, only that the dissonant sets are as a rule not widely used, but are used with special precautions only

A set of notes with a given relationship in our ordinary language however means a scale Hence the Western system uses only the consonant scales, of which the notes belong to a cycle of harmonic relationship which starts from and returns to the tonic note itself Its field of action is therefore restricted to the province of these harmonic scales only, with the result that it cannot introduce discords or quarter tones as quickly and effectively as in Indian music Notes foreign to the scale have to be first prepared for before being introduced and have then to be resolved for making a return to the original scale This is really a very laborious process and requires transposition to different keys In Indian music on the otherhand, the Rāga scales freely choose discordant notes as legitimate members of the scale, and thus allow a facility and quickness in introducing discords wherever needed This makes the appeal of Indian music almost instantaneous,

—though of a set type also, as no transposition or divergence from the chosen scale is allowed.

The adoption of harmony as the principle of style, has reduced the choice of scales to two viz. the Major mode and the Minor mode and has deprived the Western system of a great variety of expression which depends on a diversity of scales. But this has opened to that system new avenues of artistic design, in another quarter. Indian music on the otherhand, with its numerous scales, is very rich in the field of melody, but cannot change its mood as it has to stick up at one time to one given scale only, and although the use of a drone lightly hints at the principle of harmonic relationship, has no harmony at all in the Western sense of the word.

As for the relative merits of each system the best way is to reproduce what Dr. Helmholtz says at one place, "We must not forget that our modern system was not developed from a natural necessity but from a freely chosen principle of style; that beside it and before it other tonal systems have been developed from other principles and that in such systems the highest pitch of artistic beauty has been reached by the successful solution of more limited problems."

The Drone as the starting point of Indian music :—

In a previous chapter attention was already drawn to the various difficulties in the way of arriving at the Shuddha-scale of Indian Music and in adopting that scale as the basis of reference for the purposes of fixing its intonation. These difficulties

however are of a theoretical character only and lose most of their acuteness in practical music, as every student of the art first learns it by the ear-method and hence unconsciously masters all the desired niceties of intonation as required by each particular Rāga. To keep his sense of tonality firm and quite in tact, he further uses a simple device of employing the drone as an essential harmonic background to his music. His ideas of intonation are *therefore linked* up with the scales of specific Rāgās in relation to the background of the drone. His language of intonation also goes by Rāga-scales and not by vibration numbers or intervals. When he means a particular degree of sharpness or flatness of a note, he invariably *refers to* it as the note corresponding to *such and such a note in such and such a Rāga* and so on. Thus it is that with the help of a few well-known Rāga-scales he fixes his ideas of intonation. But as there are only seven—at most twelve—common names by which the seven notes of the octave are known, all these different variations in the form of a note are broadly known by one of these seven—or twelve—stock names But this must not be taken to mean that music uses these seven—or twelve—notes only, and does not use others besides them Nor does it mean that if it uses other notes, then their variations are so small that for all practical purposes they can be conveniently neglected On the otherhand, it is found that a student of Indian music,—and one even of a very moderate capacity for that matter,—ordinarily uses a much larger number of notes than twelve and all these are appreciated and felt by the ear, as distinctly

different notes, both individually and in their relation to the several Raga scales, also Yet Pundit Bhātkhande bases his system of Hindusthāni music on twelve notes only Mr Clements is therefore justified when he refers to Pnndit Bhātkhande and remarks that though 'the exponent of the Art of Melody recognises twelve notes only, the Art of Melody must not be confused with intonation or the Science of the Shruti' So, Mr Clements made it a point to verify the scale of each individual Rāga, with the help of a Diehord, and demonstrated in a practical manner the truth that Indian music uses a far larger number of notes than twelve Of course the method has a great academic value, hut is not in any way connected with any surviving ancient practices Nor does it hint at a central principle which serves as a base of all the physical or æsthetic processes of the Indian system

In the present work, however, the employment of a drone as a necessary back ground, for all music, has been made the basis of nll the processes of the system nnd of the conditions governing the Rāga system also As already mentioned elsewhere, the practice of employing a drone is a very ancient practice and still serves as the very basis for maintaining the sense of tonality of the present-day music also Further it gives the essential consonances of the system and discloses that in Indian Music there is no scale which is ideally consonant and which at the same time obeys the condition of symmetry in its two tetrachords—a condition which every Rāga-scale is required to obey The Shuddha

scale of Indian Music is not therefore an ideally consonant scale. In practice also, we do not come across a Rāga which employs a perfectly consonant scale, such as the one given by the Major Mode of the West. The scales of Indian music are then chosen in a more or less free manner. Again, the observance of the rules governing the Rāga-system is not a matter of natural necessity but is the consequence of referring that system to the accompaniment of a drone. If the drone were tuned in ways other than the conventional one, then even though a Rāga-scale may remain the same in point of the pitch and intervals of the several notes, its character does undergo a total change. This means that the standard of tonality changes according to the change in the tuning of the drone, or that the tonality of Indian music is not of a fundamentally fixed character but appears so, because of the conventional manner of tuning the drone. This is why the drone was given the first place among the unities of Indian music.

Besides the conventional ways of tuning the drone, it may be tuned in other ways also, such as by taking the other notes of the scale, for the auxiliary note. Thus the drone is sometimes of the E-type, and is employed in Rāgās which omit both the major Fifth and the major Fourth, and take the major Third as one of their principal notes. In such cases the drone does not make much difference in effect for that particular Rāga, but if employed for others, in which the major Third is either absent or has not the same significance attached to it as in the former, the effect is beyond doubt different and in most cases spoiled also. This

is perhaps the reason why the third type of tuning viz the one according to the Gandhār Grāma, was abandoned even from the very ancient days Yet from the academic point of view, it is desirable that the student should experiment with all possible types of tuning the drone This will at once bring to his notice that theoretically many different schemes of tonality are possible, and the two in vogue, being the most harmonious of them all, are consequently adopted as the standard ones Of the two again, the tonality of the G-type being the simpler and more direct is naturally adopted for almost all the Ragas and that of the F type, in exceptional cases only

Yet another variation of the drone is to tune the auxiliary wire to the note which a Raga essentially omits and transpose the music to the auxiliary note as a new base In Malkansa, for instance, which *omits the major Fifth, the conventional way is to* adopt a drone of the F type But according to the present suggestion, it is to be replaced by the G type, and the music is to be transposed to the note G, serving as a new base It is found that this lends a new charm to the Rāga, without spoiling any of its beauties, and allows transposition at will between the old and new *bases also* Similarly in Bhupa, which omits the major Fourth the drone may be taken as of the F type-and not of the G-type, which is conventionally employed for that Raga If the music is then transposed to the note F, given by the auxiliary wire as a new base, the effect of the Raga is not at all spoiled but turns out to be really pleasant and of a novel *character also Of course such cases may* not

be very large in number, but a knowledge of the process may easily bring to the notice of the student the significance of transposition in music, and may perhaps open some new field for extending the present-day-Rāgās in other quarters also

Retrospect.

Indian music is a very ancient art and has an interesting history behind it As in the evolution of the other arts, feeling, fancy and inspiration played a great part in its early development and science came on the scene much later Hence it is, that science is unable to explain some of the earlier practices, and their justification comes through tradition, inheritance or association only. This being so, the Theory of Indian music could not at any stage of its evolution reconcile itself wholly with the practice of the Art. The ancient writers however felt a necessity of bringing the two as close together as possible and in doing so resorted to ways and means, which sometimes resulted in diametrically opposite interpretations of one and the same thing Again a growing art was bound to undergo many changes in the course of its development The above causes explain why the theory and practice of Indian music did not always go together hand in hand, and why the writers on Indian music, belonging to different epochs of time, could not but widely differ from one another Another great ordeal, through which Indian music had to pass, was the reaction of the Mohammedan culture But as we now see, its contact with the Mohammedan culture only extended its possibilities but allowed its essential features to remain in tact, for the

apparent reason that the foundations of the art had become sufficiently solid by that time and that most of the first generation of the Mohammedan artists were elderly Hindus, later on converted to Islam Last but not the least our contact with the sciences of the West, had its own reactions—among other things—on Indian music also, and has provided us with specific and more critical standards of judgment As a result, it may be said that Indian music is largely benefitted by this contact and so far at least has no cause for any repentance for the same

Music, in general, forms a most necessary link in the great family of Arts and every student of it ought to know the nature and limitations of its function For the purposes of an academic study like the present, music must be studied as a pure art and not in its relation to the other arts

Music is the least material of all the fine arts and has a much greater and more absolute freedom in shaping its material in its own way than the rest of them Thus Beetboven used to say that 'Words are bound in chains but happily sounds are still free, and almost all good artists are bound to feel the same way sometime or other But as has already been remarked in the second chapter, musical sound is not completely free to have its own way and before being able to discharge its higher function as an art has to obey certain physical laws of a universal nature Hence it is said that music is a dual entity and though an art by nature, is a science as a matter of exigency As a science it has to follow the fundamental laws of musical sound which are the result of purely physical

causes and observation and so are universally true. Though it was long, before the laws were known in their modern form, they seem to have always functioned in one form or the other in all known systems of music. This is the reason why the different systems do not materially differ in their view of the general principles of the musical science. The real point of difference between one system and another arises however, when it is desired to harness these laws to artistic effect. Here there is great scope for personal choice and as previously described, *one may adopt any free principle of style as one's starting principle.* The choice of such a free principle necessitates the creation of certain unities governing the system. The guiding principle of Indian music is the execution of all music in a given or chosen Rāga throughout and to explore the melodic possibilities of that Rāga, in all their details. This principle, when accepted as the one to start with, requires the choice of an accompaniment like that of the drone or else its tonality cannot remain the same for want of any standard of reference. The choice of a drone again has its own repercussions on the Rāga-system and this is how the first two unities are linked up together. These two with the help of rhythm, make for the larger unity of Indian music. The first two unities supply the physical quality and mood to the music, while rhythm, the third unity, supplies the emotion and governs its rise and fall. As for the artistic pleasure provided by music, it is the result of its appeal both to the intellect as well as the emotions, and that music is considered to be the best, in which there is a happy combination and equipoise

of these two factors The development of the scientific side of music has immensely widened the scope of the intellectual element in music, while the emotional side is governed by the physical, psychological and cultural associations of mankind

The Æsthetics of music has therefore to deal with both these aspects of the appeal

The processes governing the intellectual side of music are based upon the correct observance of the scientific principles in general and of the chosen unities in particular, the emotional side has however a very limited field to start with, as at first, music has nothing beyond consonance or dissonance to offer in that respect The appeal may therefore be either pleasant or unpleasant but cannot specify a particular emotion as such This inability of music is however removed by supplementing the pleasant or unpleasant effect by the tonal and rhythmic variations, which awaken certain psychological associations and experiences, which lead the mind into the sphere of parallel activity and experiences from life The appeal becomes still more specific, if it is further associated with certain cultural practices Thus, music if used for prayer will be considered to be devotional or if used for mourning as sad and so on Here however there is some need for a little caution, as on its own merits such music may or may not be really devotional or sad, but the force of the cultural practices may often be so great as to dictate the mood to music In such cases, music being yoked to utility loses its significance as an art and simply becomes the handmaid

or tool of the cultural practice. So, in the realm of music, as a pure art, there is a limit beyond which cultural associations or poetry—if allowed a free hand—may replace the processes of music by those belonging to themselves and present such music in which the element of music itself is altogether absent !

In order to give full expression to its manifold beauties, Indian music has developed different forms of musical composition and each of them is associated with some special form of musical expression These forms however are not elastic enough to admit of a treatment, which the light music of today needs. There is therefore a tendency to coin out new forms of composition—which however are not really new but are evolved out of the fusion of some popular folk-tune with one of the classical type Naturally, such compositions do not employ any one Rāga in particular, but pass from one to another in a free manner and often adopt tunes from European music also How far this may have its reactions on the individual character of classical Indian music, is for the future to decide But there is at least one encouraging sign of the times that simultaneously with this bid for freedom, the number of persons taking to the academic study of Indian music is also increasing day by day and promises to maintain intact the high and noble traditions of classical Indian music, in spite of these loose tendencies of today.

Translation :—In (obtaining) the Madhyama-Grāma, the Pancham (the Fifth) is to be lowered by one Shrutee, the difference between the higher (true) and lower Pancham is the Pramān Shrutee and is equal to the Mridu and Āyatā (Jaties) states (of a Shrutee interval). We shall now explain how to demonstrate (it), as follows :—Let two Veenās, exactly alike in point of the nature and length of the strings etc. be tuned (alike) in the Shadja-Grāma. One of them should now be adjusted to give the tuning of the Madhyama Grāma (i. e. by lowering its Fifth by one Shrutee). Next keeping this altered Pa (Fifth) as it is, so lower the other notes as to make this Veenā give the Shadja-Grāma—type of notes. This is the first dimunition by a Shrutee. By a second dimunition, the Ga and Ni of the altered Veenā, become (coincide with) Ri and Dha of the standard one. By a third dimunition the Ri and Dha of the altered Veenā become the Ga and Pa of the standard one. Lastly by a fourth dimunition the Pa, Ma and Sā, (of the altered Veenā) become Ma, Ga, Ni respectively of the standard one—on account of a (total) lowering by four Shrutees. In this manner the twenty-two Shrutees of both the Grāmās should be verified, by means of this method of Shrutee demonstration.

पृ १८६ ibid रागविवेकाध्याय

(b) How this Madhyamadi happens to be a variety of Saranga is explained at length in the article referred to in (7b) above

9 Ahobala s method of tuning the successive notes of the scale, by taking different lengths of a wire under constant tension

Ahobala s rule —

षड्जपञ्चमभावेन षड्ज ज्ञेया स्वरा बुधै ।
गतिभावेन गान्धारे मध्यमे प्रसभावत ॥

The learned should know that the notes (in the two tetrachords) are related by the interval of a fifth, such as Sa and Pa, Ga and Ni, Ma and Sa etc (in the three respective Grāmās)

Verses about the relative lengths for the notes –

स्वरस्य हेतुभूताया वीणायाश्चाक्षुषत्वत ।
तत्र स्वरविबोधार्थं स्थानलक्षणमुच्यते ॥
ध्वग्रावच्छिन्नवीणायां मध्येतारक स स्थित ।
उभयोषड्जयोर्मध्ये मध्यम स्वरमाचरेत् ॥
त्रिभागात्मकवीणायां पञ्चम स्यात्तदग्रिमे ।
षड्जपञ्चमयोर्मध्ये गान्धारस्य स्थितिर्भवेत् ॥
सप्तमो पूर्वभागेच स्थापनीयोऽथ रिस्वर ।
सप्तमोर्मध्यदेशेतु धैवत स्वरमाचरेत् ॥
तन्नांशद्वयसत्यागान्निषादस्य स्थितिर्भवेत् ॥ शुद्ध स्वरा ॥

The places (nodes) for each note are described on the Veenā, which generates the notes and which can be (duly) seen with the eyes The node for the upper Sā or Octave, stands at the midpoint of the open wire, and that for the Ma (the Fourth) should be taken midway between those for the two, (the fundamental and its Octave) Dividing the wire length into three equal parts the Pancham (the Fifth) is obtained at the first division near the top The Gāndhār (the Third) is obtained mid-way between the fundamental and its Fifth, the Ri (the Second) is to be placed at the first (of the three divisions) between Sā and Pa, while the Dha (the Sixth) is to be placed between the Fifth and the Octave Again Nishada is at the end of the second (of the three divisions) between the Fifth and the Octave Accordingly the length of the

wire for each note can be easily calculated Thus taking the length as 36 inches and the vibration number as 240 for the fundamental or Sā, the lengths and frequencies of the various notes of the Shuddha scale, according to Ahobala may be written as —

Note	Length	Frequency
Sa (C)	36"	240
Re (D)	32"	270
Ga (E)	30"	288
Ma (F)	27"	320
Pa (G)	24"	360
Dha (A)	21⅓"	405
Ni (B)	20"	432
Sa (C)	18"	480

The nodal position for Dha is not specifically stated by Ahobala and hence there is great difference of opinion on that point, among the Pandits "But as Ahobala states in his first rule that the notes in the two tetrachords are to be at an interval of a Fifth, it seems fair to grant him the benefit of doubt and assume that he well knew the required position for Dha This is the latest view taken by scholars

10 There were numerous Mātas or schools of musical lore These were — Shiva mata Krishna mata Bharat mata Hanuman mata Kallinath mata, Someshwar mata, Indra prastha mata and many others The first four were very ancient and of them also the first two were long out of date even in the days of the Naghamate Asafi Even the Bharat and the Hanumān-matās were not then well understood and hence the attempt on the part of Mohomed Raza, to write the Naghamate Asafi

Each Mata started with six basic Rāgās so as to respectively represent the six parent-scales, which were thought to be essential for developing the system in full (For further information on the point, please see Chapter VI page 89)

11 C/o comments on page 19 Rāgās of Tanjore by E Clements (I C S Retired)

CHAPTER III

1 (a) *Bharata and Matanga consider the Shrutees to be of five different varieties with five different intervals, but do not mention anywhere the proper names assigned to them.*

(b) Shārangdev and the later authors however mention the proper names of the twenty-two Shrutees, *and state that the Shrutee-intervals are of five different kinds or Jaties*

दीप्तायता च करुणामृदुर्मध्येतिजातय ॥

संगीत रत्नाकर ॥

* Verse 29 Page 41 *

Verses 30–39 (page 41–42) of the Sangeeta Ratnākar—Anandashram-Edition, give the proper names of the Shrutees, in their serial order, as —

1 तीव्रा, 2 कुमुद्वती 3 मन्दा 4 छन्दावती	} For C (सा)
5 दयावती, 6 रजनी, 7 रक्तिका	} ,, D (रे)
8 रौद्री, 9 क्रोधा	} ,, E (ग)
10 वज्रिका, 11 प्रसारिणी, 12 प्रीति, 13 मार्जनी	} ,, F (म)
14 क्षिती, 15 रक्ता, 16 संदीपनी, 17 आलापिनी	} ,, G (प)
18 मदन्ती, 19 रोहिणी, 20 रम्या	} ,, A (ध)
21 उग्रा, 22 क्षोभिणी	} ,, B (नी)

Of course the frequencies of his notes are not known and should not therefore be taken to be those ordinarily represented by the letters C D E F etc.

Chapter IV

Samples of recitation and folk songs

Prayer —to oneself

	राम,	राम,	राम,	राम, . etc	Thus is literally mono tonous
Notation —	ग, सा,	सा, सा,	मा, सा,	सा, सा, . etc	
	Rām	Rām	Rām	Rām . etc	
Notation—	Sa, Sa,	Sa, Sa,	Sa, Sa,	Sa, Sa etc.	

Prayer —in public.

Ex. 2.

	राम राम	राम राम	सीताराम	सीताराम
Notation —	सा सारे-	ग-ग-	रे-ग रे-	सा-सा सा-
	Rām Rām	Rām Rām	Sita-Rām	Sitā Rām.
Notation —	Sa, sa, re-	ga-ga-	re-ga re-	sa-sa sa-.

The above are the usual forms for 1 and 2 respectively Variations are however often effected, but they are mere imitations of the above, only at different levels

Recitation of Metres

Indra wajrā

3

1st and 3rd lines —	देखोनि	डाव्यं	हृदयाभिरामा
	ध–सा–रे	ग्–ग–	गमग–रे सा–रे–
	Dekhoni	dola	hridayabhirama
	Dha, sa,– re	ga–gu	gu, mu, ga–re, su–re–
2nd and 4th lines —	रामापुढें	धावतसे	सुखामा
	रे–ग–सारे–	नि–सारेग–	रे सा–सा–
	Rama pudhe	Dhawatase	Sukama
	re–ga–sa, re–,	ni–sa, re, gu–	re, su–su–.

The notation of Upendra Wajrā is the same as that of Indra wajrā, the pauses alone varying according to the order of the long and short syllables of the metre

(Swāgatā and Rathoddhatā are two other metres having the same common notation and it appears that two metres having the same number of letters or syllables have the same notation, irrespective of the difference in the order of their long and short syllables)

Simple Folk-Songs

Ex 13. **Hadgā Dance—Song—No 2**

Duet.

1st line —

माझ्या	माहेरीच्या	वाकी	गुजरीच्या
प-नि-	नि नि-सा	सा,ग	रे ग रे सा
Majhya	maherichya	wāki	gujarichya
pa ni	ni ni-sa	sa,ga	re ga re sa

2nd line, question —

तुझ्या ग	माहेरच्यान	तुला	काय	दिल
सा ग- ग	ग ग ग ग	ग-ग-	ग-रे	सा रे
Tujhya ga	maherchyāna	tula	kaya	dila
Sa, ga, ga,	ga, ga, ga, ga,	ga,ga,	ga,re,	sa,re

3rd line, answer —

माझ्या ग	माहेरच्यान	मला	दिला	हत्ती
ग-ग- ग	ग ग ग ग	रेग-	रे सा-	सा सा,
Majhya ga	maherchyana	mala	dilā	hatti
ga, ga,- ga	ga, ga, ga, ga,	re, ga,	re, sa,	sa, sa.

and fresh questions and answers go on in the same manner as the above.

CHAPTER V

Explanatory note about the basic and chromatic scales used in Indian music —

The six scales given on page 72 include both the auxiliary notes F and G, and are perfectly symmetrical in both the tetrachords and employ at least five major consonances The remaining two notes also are not very remote in character

The next, in point of merit to these, is the following scale which omits G, but includes F and is (fairly) symmetrical in both the tetrachords

Scale No 7 —

C	D	E	F	F♯	A	B	c
240	256	300	320	341⅓	400	453⅓	480

These seven scales serve the purpose of all the present-day Rāgās Thus —

Scale No (1) is employed by Rāgas of the Nata group.
" " (2) " " " " like Madhyamādi
Scale No (1) and (2) together contribute the scales for the Khamaja and Bilawal groups Scales derived by combining two such scales are very similar to those of Folk music Behaga employs No (1) with ♯ in addition, the Kalyān group employs No (2) with F ♯ and B instead of F and B♭♭ respectively

Kedar employs No (2) with F ♯ and B in addition No (3) is employed by the Kāfi and allied Rāgas Nos (1) and (3) combined together contribute the

No. (5) is employed by the Bhairava-group. The Purvi-group employs No. (5) with F♯ in addition.

No. (6) is employed by Bhairavi. Todi employs No. (6) but with F♯ and B instead of F and B♭ respectively.

No. (7) is employed by Rāgās like Lalita, Puriyā, Mārawā and Hindol etc.

(1) In some Rāgās an extra note is often employed as an accidental, which however may not fit in the scheme of symmetry between the two tetra-chords. Such a note is however employed for some artistic purpose, either as a leading note or as one to distinguish that Rāga from another very close to it.

(2) Again in certain Rāgās there is usually no agreement among artists about the degree of flatness or sharpness of a note taken in a chromatic manner. These notes being chromatic in character naturally invite adaptation according to individual capacity, skill or taste and are therefore bound to be different with different people. But in all such cases the artist tacitly follows the formula of symmetry and places the other note in the other tetrachord in such a manner as to provide perfect symmetry with the note, he first chooses in the first tetrachord.

CHAPTER VII

Gamakās or Tonal Variations.

स्वरस्य कम्पो गमक: श्रोतृचित्तसुखावह:
तस्य भेदास्तु तिरिप: स्फुरित: कम्पितस्तथा ॥
लीन आंदोलितवलितत्रिभिन्नाकुलाहता: ।
उल्लासित: प्लावितश्च गुंफितो मुद्रितस्तथा
नामितो मिश्रित: पंचदशेति प्रकीर्तिता:.

In the above Shlokās, Shārangdeva mentions fifteen kinds of Gamakās or tonal variations At present there are about ten varieties in vogue and a majority of them are practised in instrumental music only The Gamakas are now known by such modern names as, Tān, Alapa, Meenda Ghasita, Palatā, Suntha, Larazā etc Most of the professionals make such variations as Gamakās, only through the force of long association and habit and only a few know their real technique
